Introduction

In Nature, there are 4 forces

Force	Carrier	Range	Relative Strength
Strong	g	10^{-18}m	1
Electromagnetic	γ	Infinite	10^{-2}
Weak	W^{\pm}, Z^0	10^{-15}m	10^{-13}
Gravity	G	Infinite	10^{-38}

In particle physics, we usually focus on first three since gravity is so much weaker

e.g., gravitational attraction between two electrons is $\sim \times 10^{42}$ weaker than EM repulsion

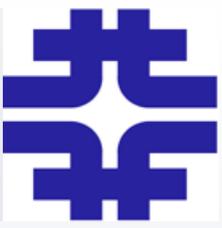

Introduction

- While it may be safe to ignore gravity at EWK energies, there are places where all forces should be relevant (e.g. Big Bang)
- At very high energies, all 4 forces should unify
- Gravity unites with other forces at the Planck Scale (10^{19} GeV)
- Hierarchy Problem:
 - Why is EWK scale so different from Planck scale?
 - Alternatively, why is gravity so much weaker than other forces?
- Extra Dimensions could allow the fundamental Planck scale to be as low as the EWK scale

Introduction

- Large Extra Dimensions were proposed as a new solution to the hierarchy problem in the late 1990's
- Since then, LED have been invoked to explain nearly all unsolved problems of the SM:
 - EWWSB
 - Dark Matter, Dark Energy
 - SUSY breaking
 - ...
- Extra Dimensions must be somehow hidden or we would have seen them already
- Either compactified or inaccessible to some part of SM

Only a partial list of models

ADD Model:

 Arkani-Hamed, Dimopoulos, and Dvali

 [Phys.Lett. B429\(1998\)](#), [Nuc.Phys.B544\(1999\)](#)

 n extra dimensions, compactified at radius R

 SM is confined to brane in a higher dimensional space

 Only gravity can access extra dimensions

 Signatures:

 **Jets+Missing E_T** , γ +Missing E_T , lepton pairs

Randall-Sundrum Model:

 PRL**83** 3370(1999)

 One warped extra dimension

 Two branes, gravity localized on one, SM localized on second

 Signature: Narrow, high mass resonances

Universal Extra Dimensions

 Phys.Rev.**D64**:035002 (2001)

 One or more extra dimensions of TeV^{-1} size

 SM particles allowed to live in bulk

 Signature: Excited gauge bosons

Gravity in Extra Dimensions

Gravitational Potential in 4 Dimensions (Newton)

$$V(r) = G_N \frac{m_1 m_2}{r} = \frac{1}{(M_{Pl})^2} \frac{m_1 m_2}{r}$$

Gravity in Extra Dimensions

Gravitational Potential in 4 Dimensions (Newton)

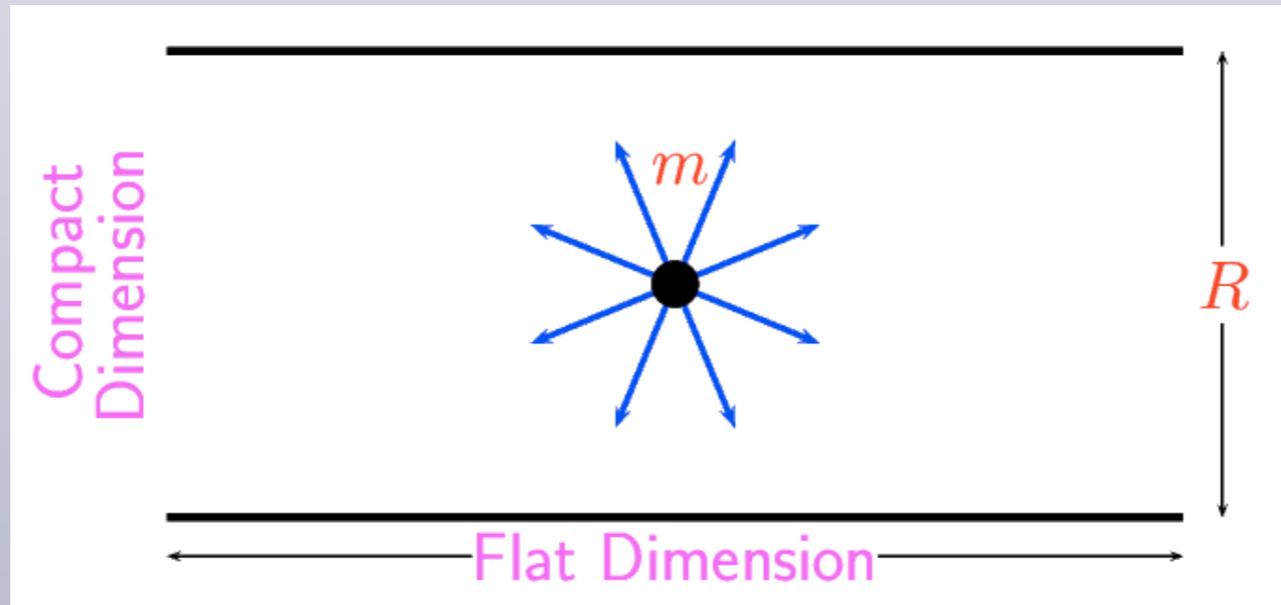

$$V(r) = G_N \frac{m_1 m_2}{r} = \frac{1}{(M_{Pl})^2} \frac{m_1 m_2}{r}$$

n extra dimensions, compactified at radius R

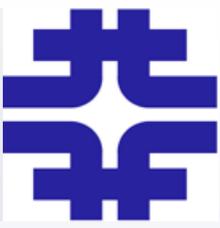

$r \ll R$

$$V(r) \sim \frac{1}{(M_D)^{n+2}} \frac{m_1 m_2}{r^{n+1}}$$

Gravity in Extra Dimensions

Gravitational Potential in 4 Dimensions (Newton)

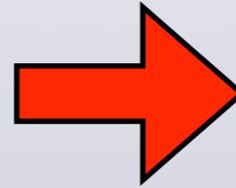

$$V(r) = G_N \frac{m_1 m_2}{r} = \frac{1}{(M_{Pl})^2} \frac{m_1 m_2}{r}$$

n extra dimensions, compactified at radius R

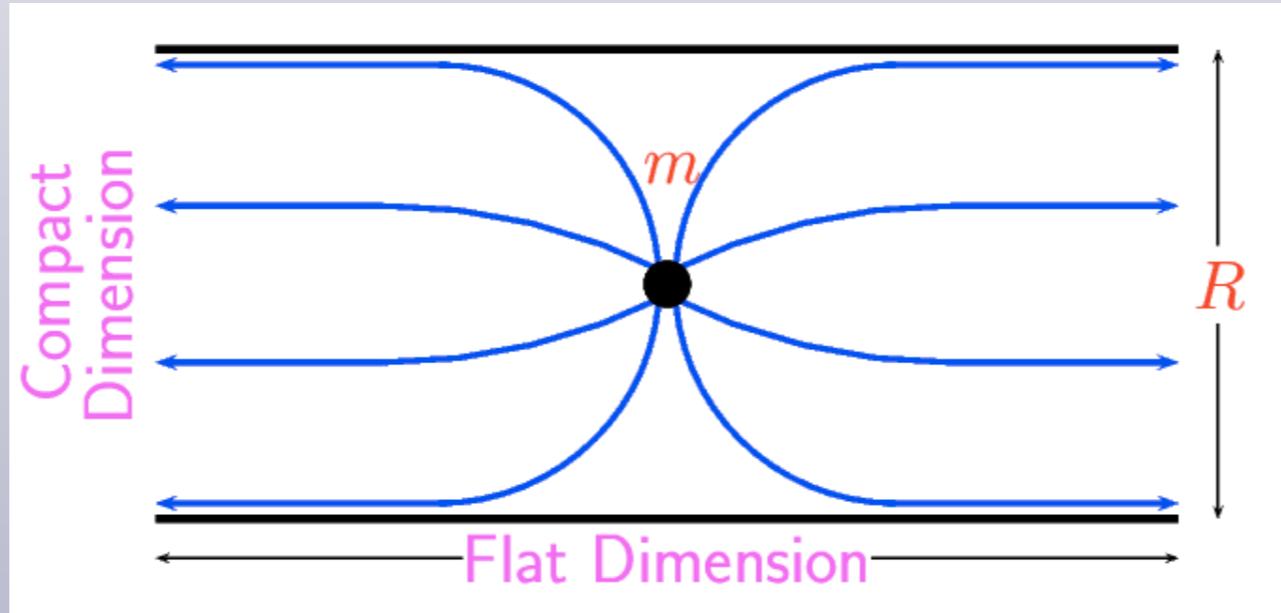

$r \ll R$

$$V(r) \sim \frac{1}{(M_D)^{n+2}} \frac{m_1 m_2}{r^{n+1}}$$

$$V(r) \sim \frac{1}{(M_D)^{n+2}} \frac{m_1 m_2}{R^n} \frac{1}{r}$$

$r > R$

At large distances, must return to original potential

$$(M_{Pl})^2 \sim R^n (M_D)^{2+n}$$

4 dimensional M_{PL} related to the $(4+n)$ -dimensional M_D by

$$(M_{PL})^2 \sim R^n (M_D)^{2+n}$$

Setting $M_D = 1 \text{ TeV}$

- $n=1 \Rightarrow R = 10^{13} \text{ m}$

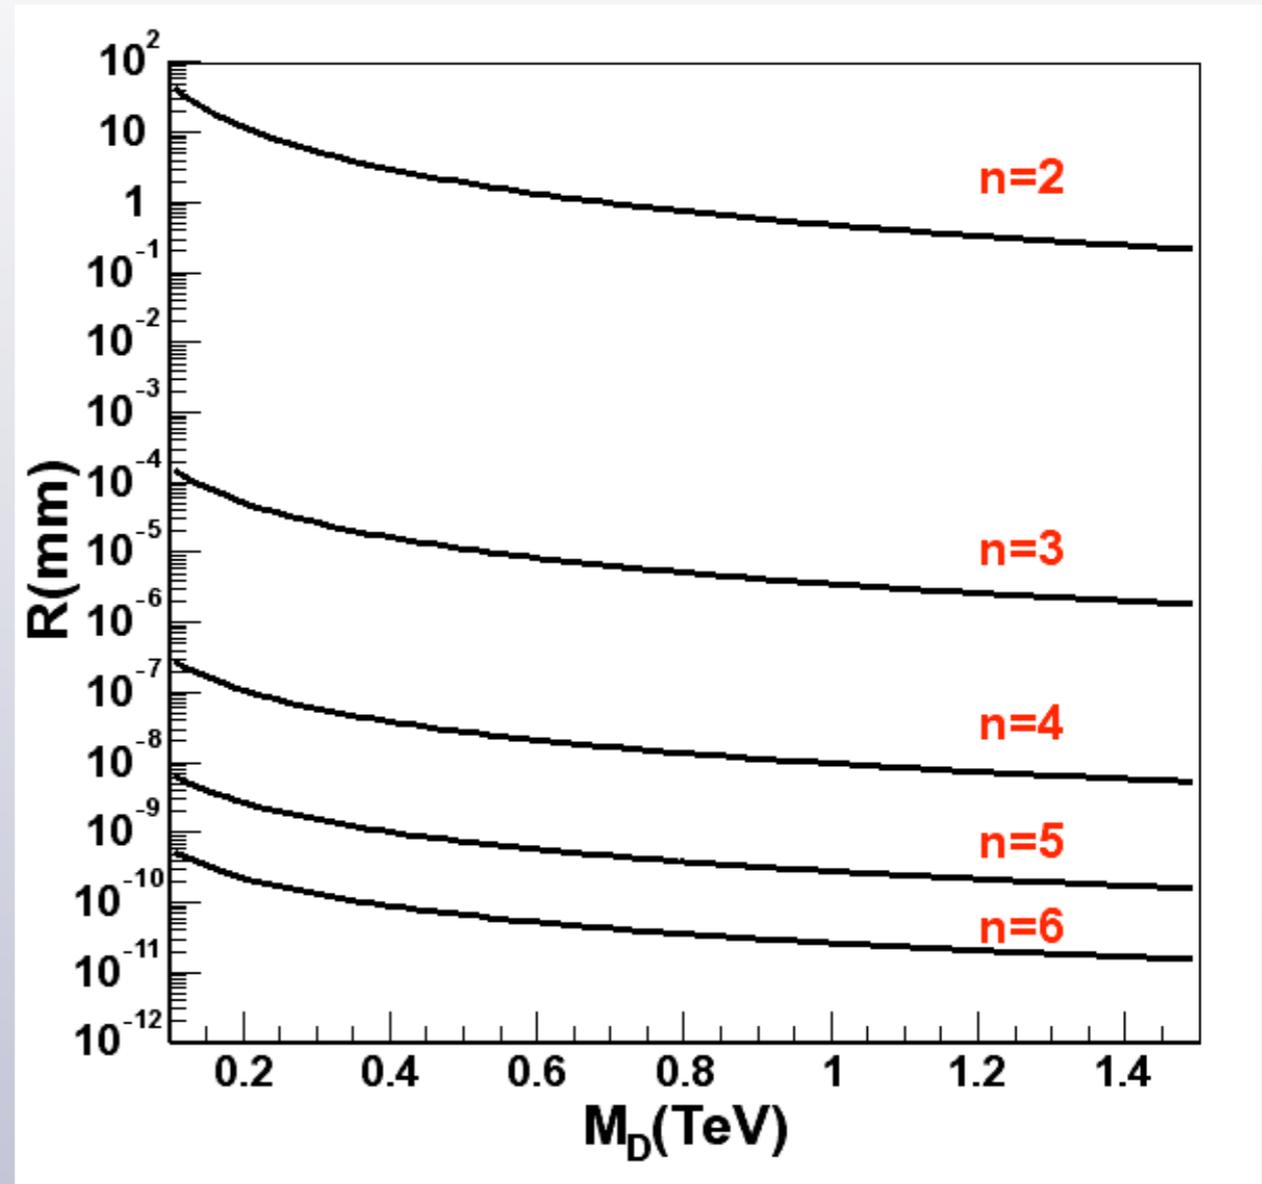

excluded by astro. data

- $n=2 \Rightarrow R \sim 400 \mu\text{m}$

same order as direct probes of gravity

- $n=6 \Rightarrow R = 10^{-13} \text{ m}$

only testable at high energy colliders

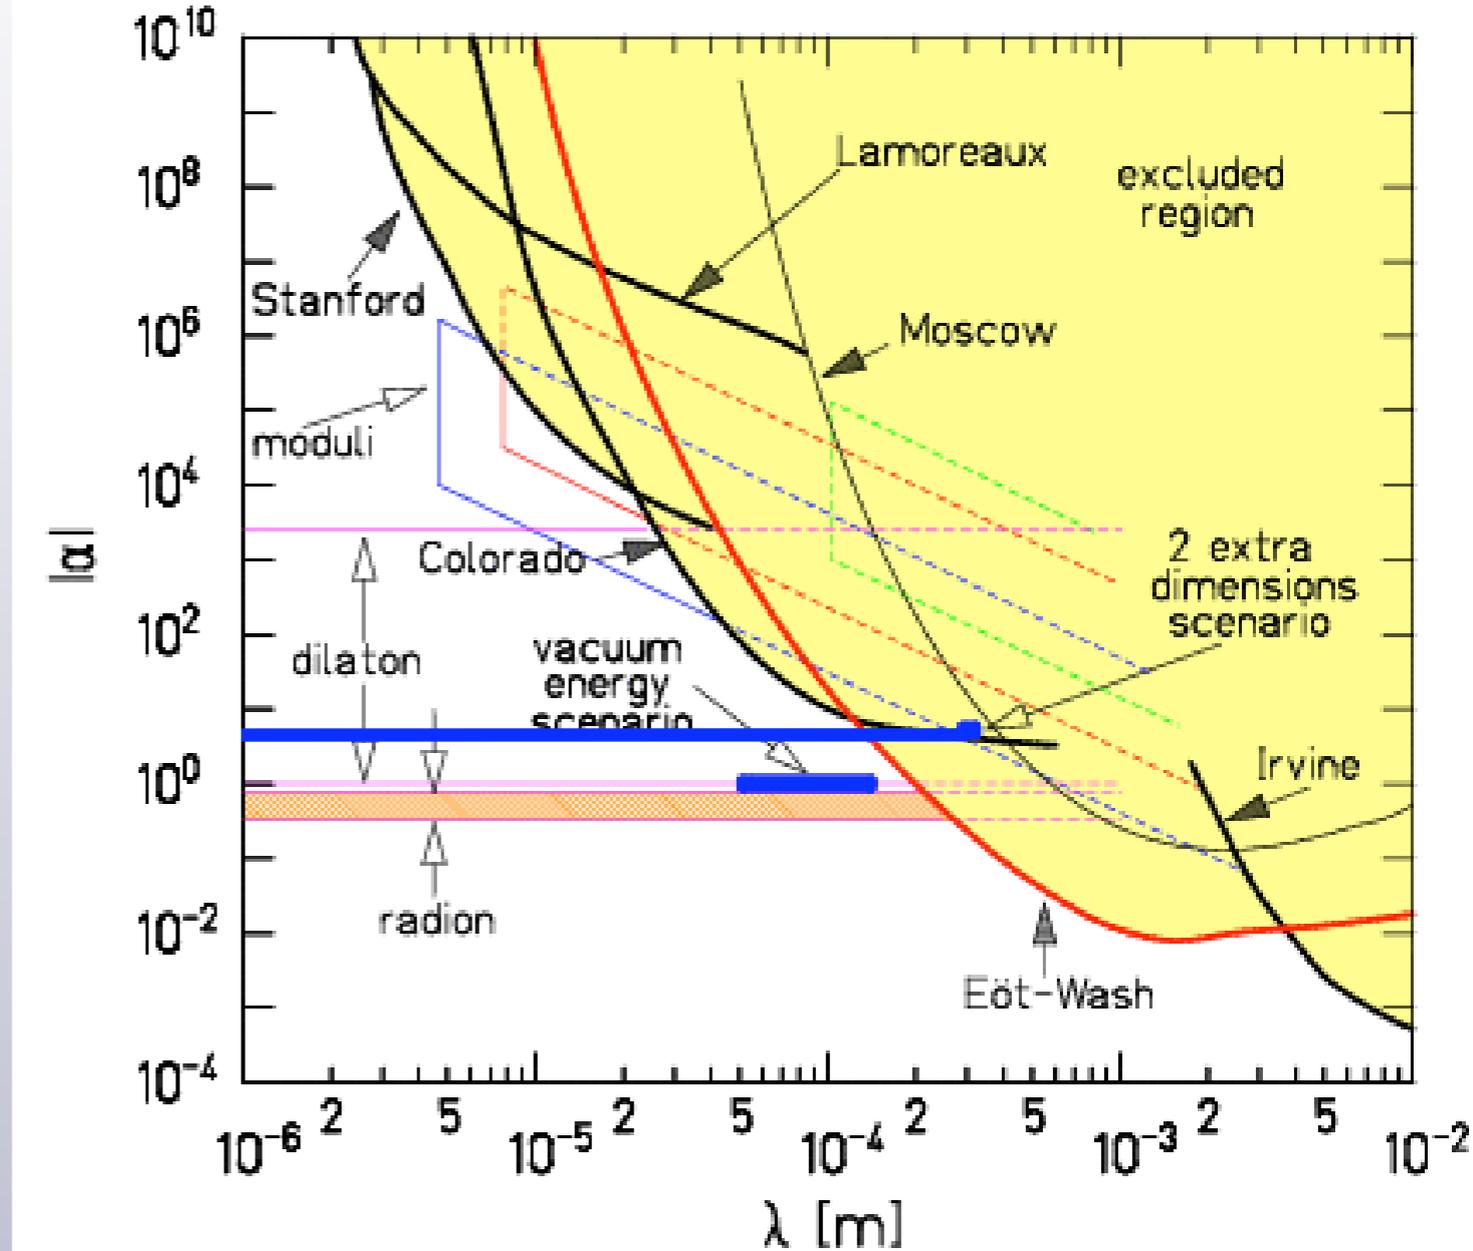

Direct Test of Short-Range Gravity

- Look for deviations in $1/r^2$ law of gravity
- Replace Newtonian potential with more general expression:

$$V(r) = -G \frac{m_1 m_2}{r} (1 + \alpha e^{-r/\lambda})$$

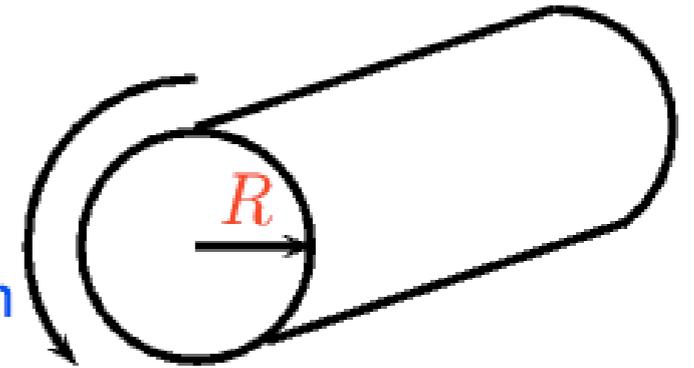

- $\lambda =$ range
- $\alpha =$ strength relative to gravity
- For the case of n toroidal extra dimensions, $\alpha = 8n/3$

Relevant Limit from Eöt-Wash Experiment: $R < 130 \mu\text{m}$ ($n=2$)
(PRD70, 042004)

- Compactified dimension is periodic
- Momentum in extra dimensions is quantized, $p=k/R$
- Gravitons appear to have mass, $m^2 = m_0^2 + p^2$
- Tower of KK modes
 - mass splittings $\Delta m \sim 1/R$
 - nearly continuous
 - $n=2: \Delta m \sim 10^{-4}$ eV
 - $n=6: \Delta m \sim 10$ MeV

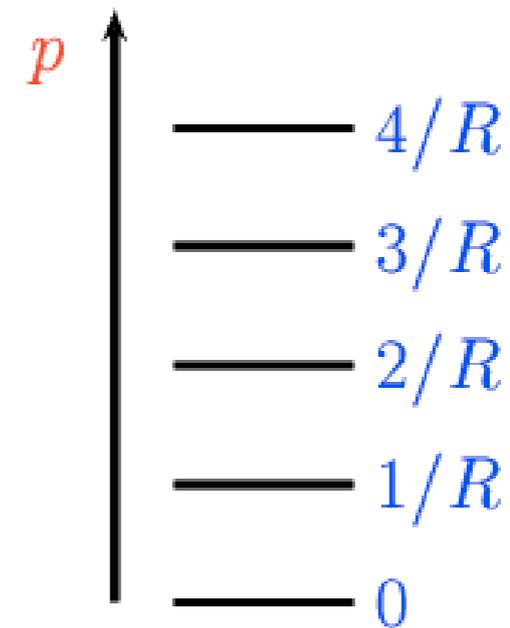

Compact
Dimension

$$\phi(x) = \phi(x + k2\pi R)$$

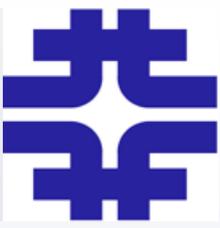

$$(k = 0, 1, 2, \dots)$$

$$p = k/R$$

Gravity in Extra Dimensions

Though each graviton couples with strength M_{PL}^{-1} , there are $(ER)^n$ possible modes

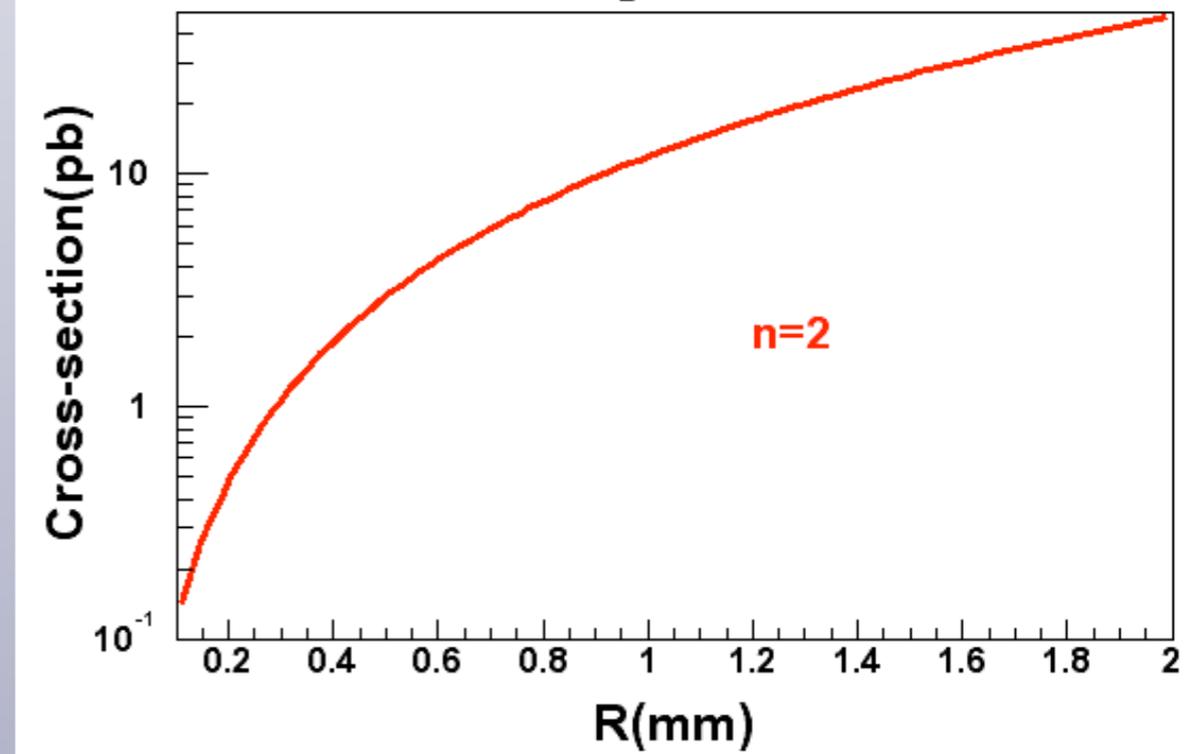

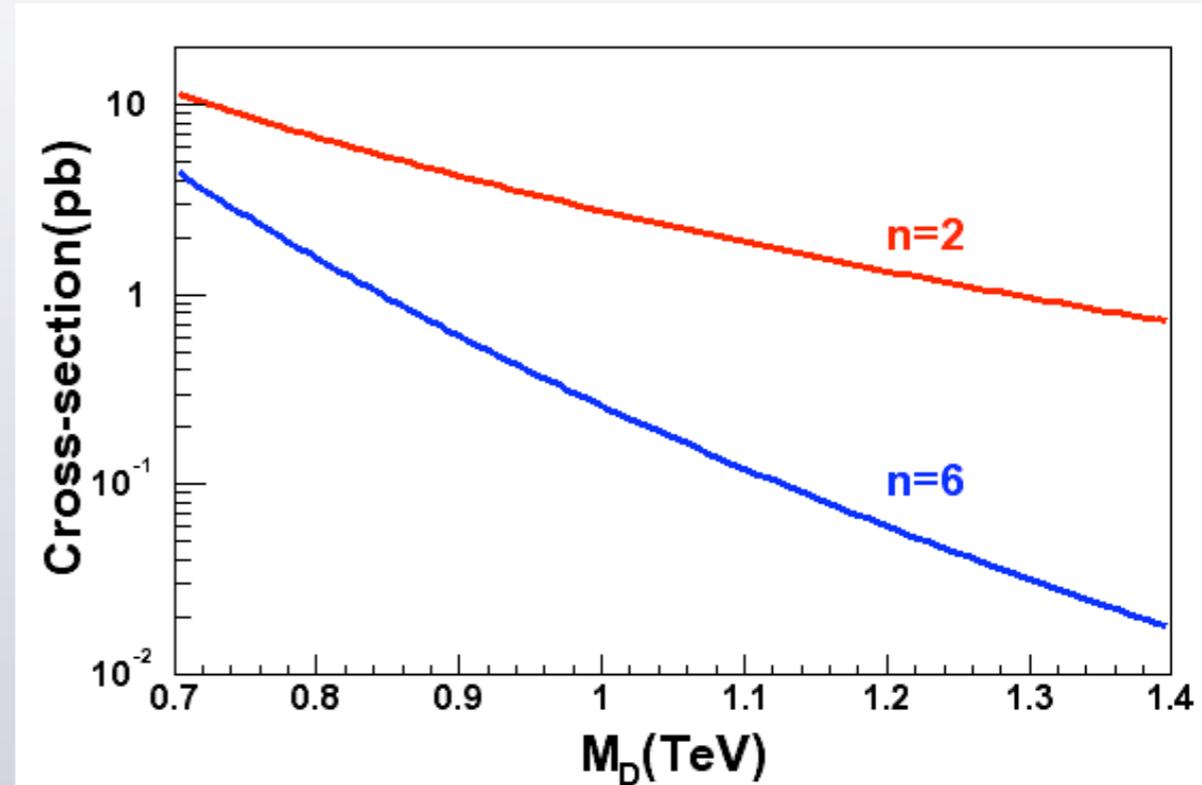

Consider cross-section for a single graviton, summed over all momenta:

$$\sigma \sim \frac{1}{M_{Pl}^2} (\sqrt{s}R)^n$$

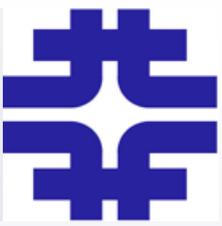

M_{PL} suppression replaced by M_D suppression

$$\sigma \sim \frac{1}{M_D^2} \left(\frac{\sqrt{s}}{M_D} \right)^n$$

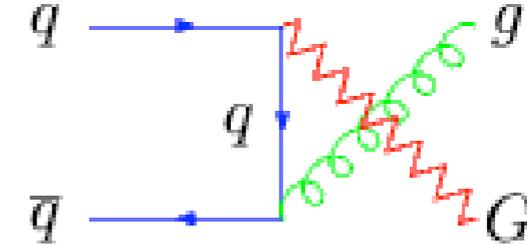

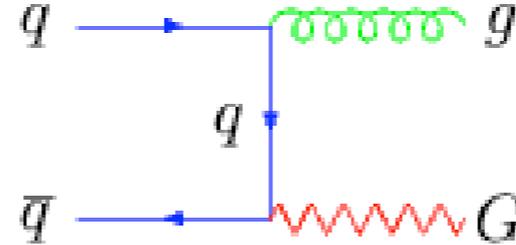

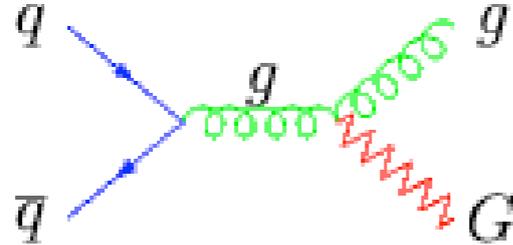

Collider Signatures of LED

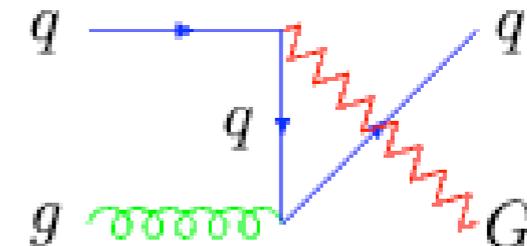

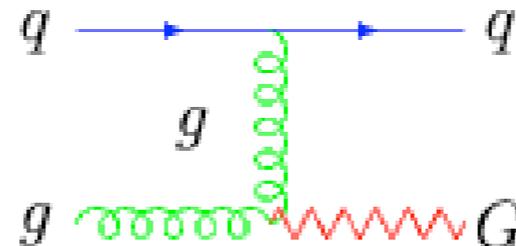

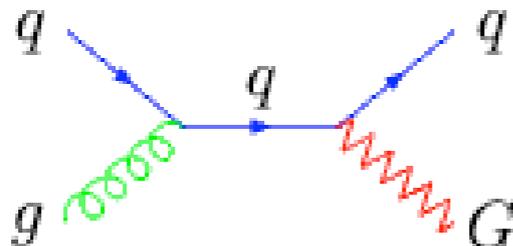

- How could we see evidence of large extra dimensions at colliders?
- Two different signatures (ADD model):
 - **Direct graviton production**
 - Real graviton emitted in final state
 - $G + \text{jet}, G + \gamma$
 - **Virtual graviton exchange**
 - pair production of leptons, photons, etc.

Real Graviton Emission

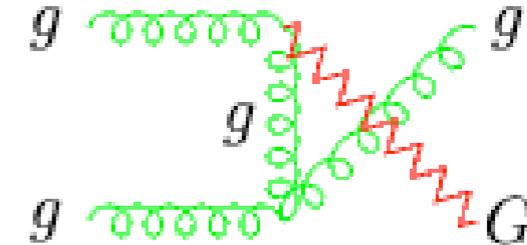

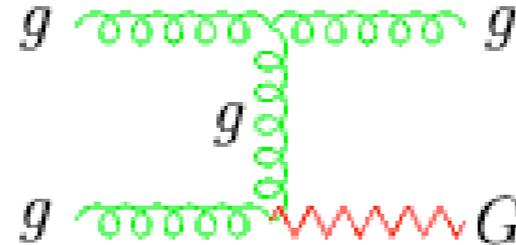

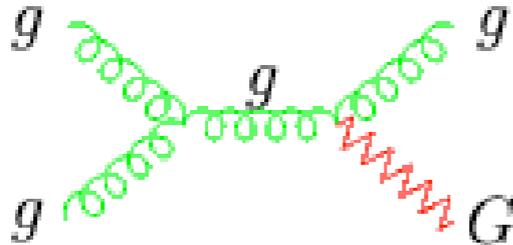

• $q\bar{q} \rightarrow gG$

• $qg \rightarrow qG$

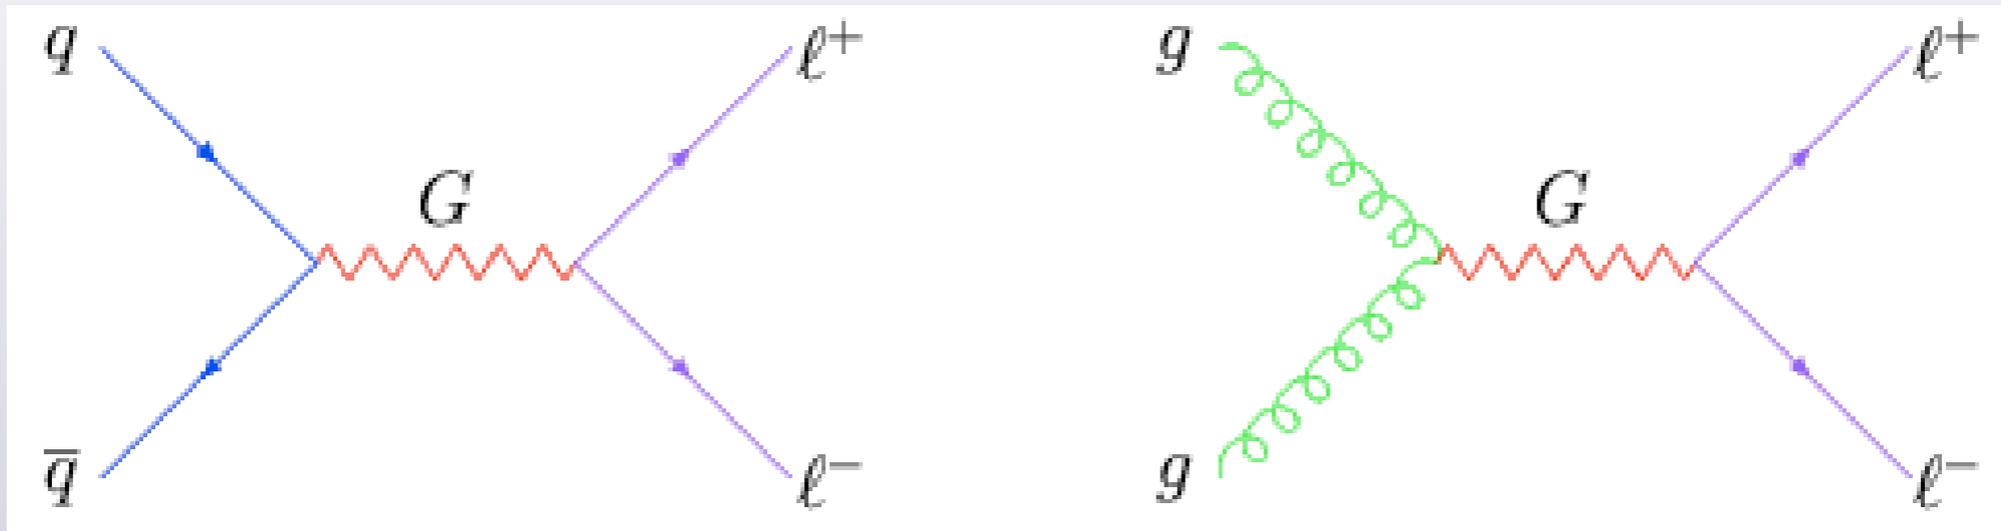

• $gg \rightarrow gG$

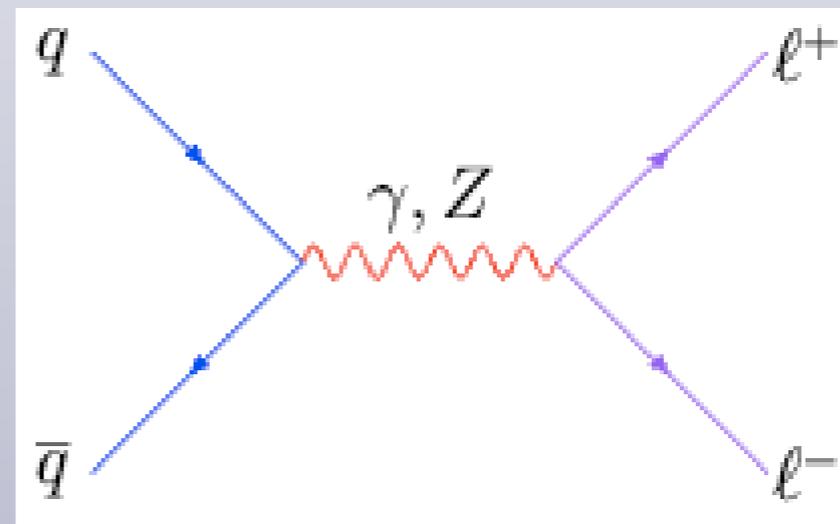

Undetected graviton leads to Missing E_T

Virtual Graviton Exchange

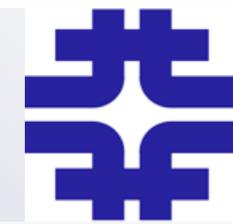

Interference from
Standard Model

Graviton exchange is more model dependent
than graviton emission due to cutoff scale

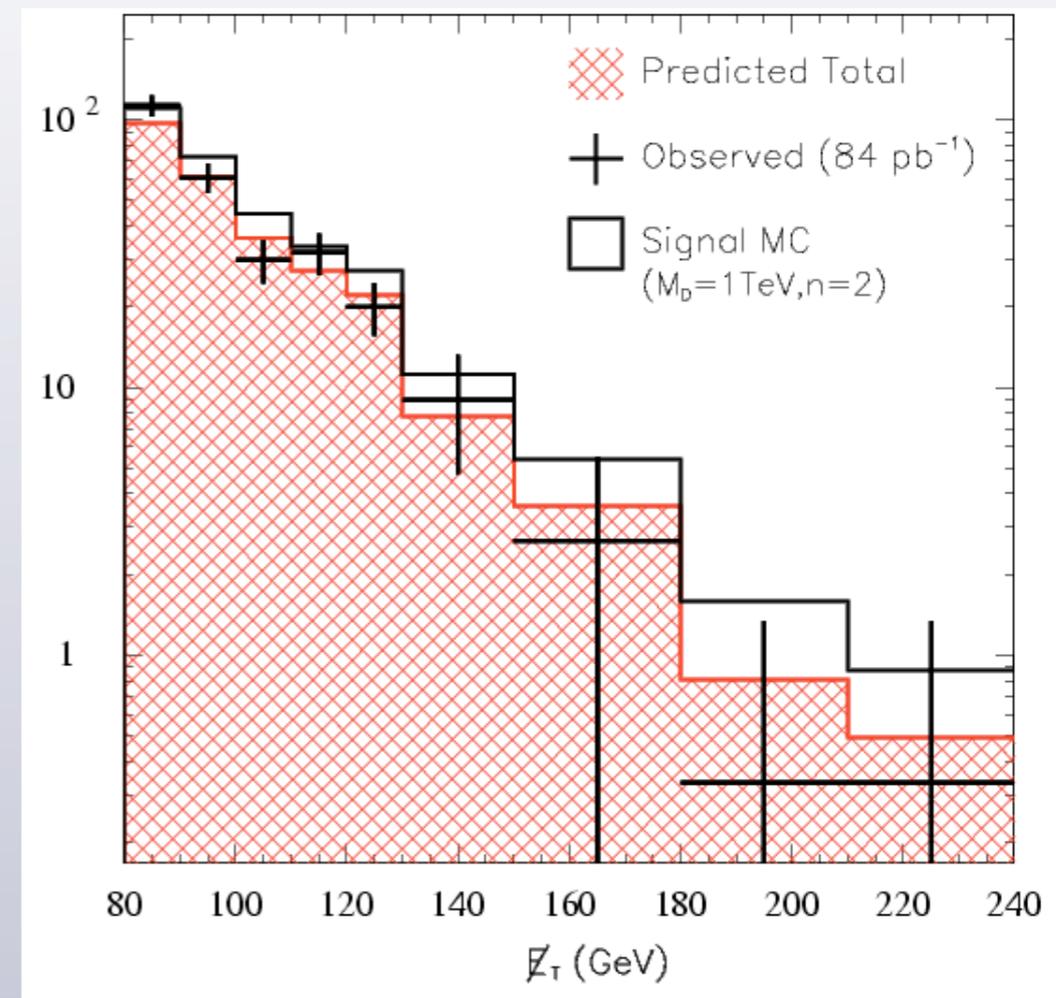

Summary of Existing Limits

CDF RunI

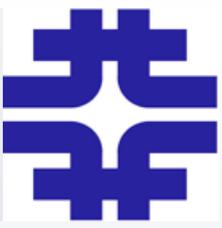

M_D Limits (TeV) From Monojet Searches in RunI:

n	CDF	D0
2	1.06	0.99
4	0.80	0.73
6	0.73	0.65

Limits on $M_S(\sim M_D)$ From RunII Virtual Graviton Searches

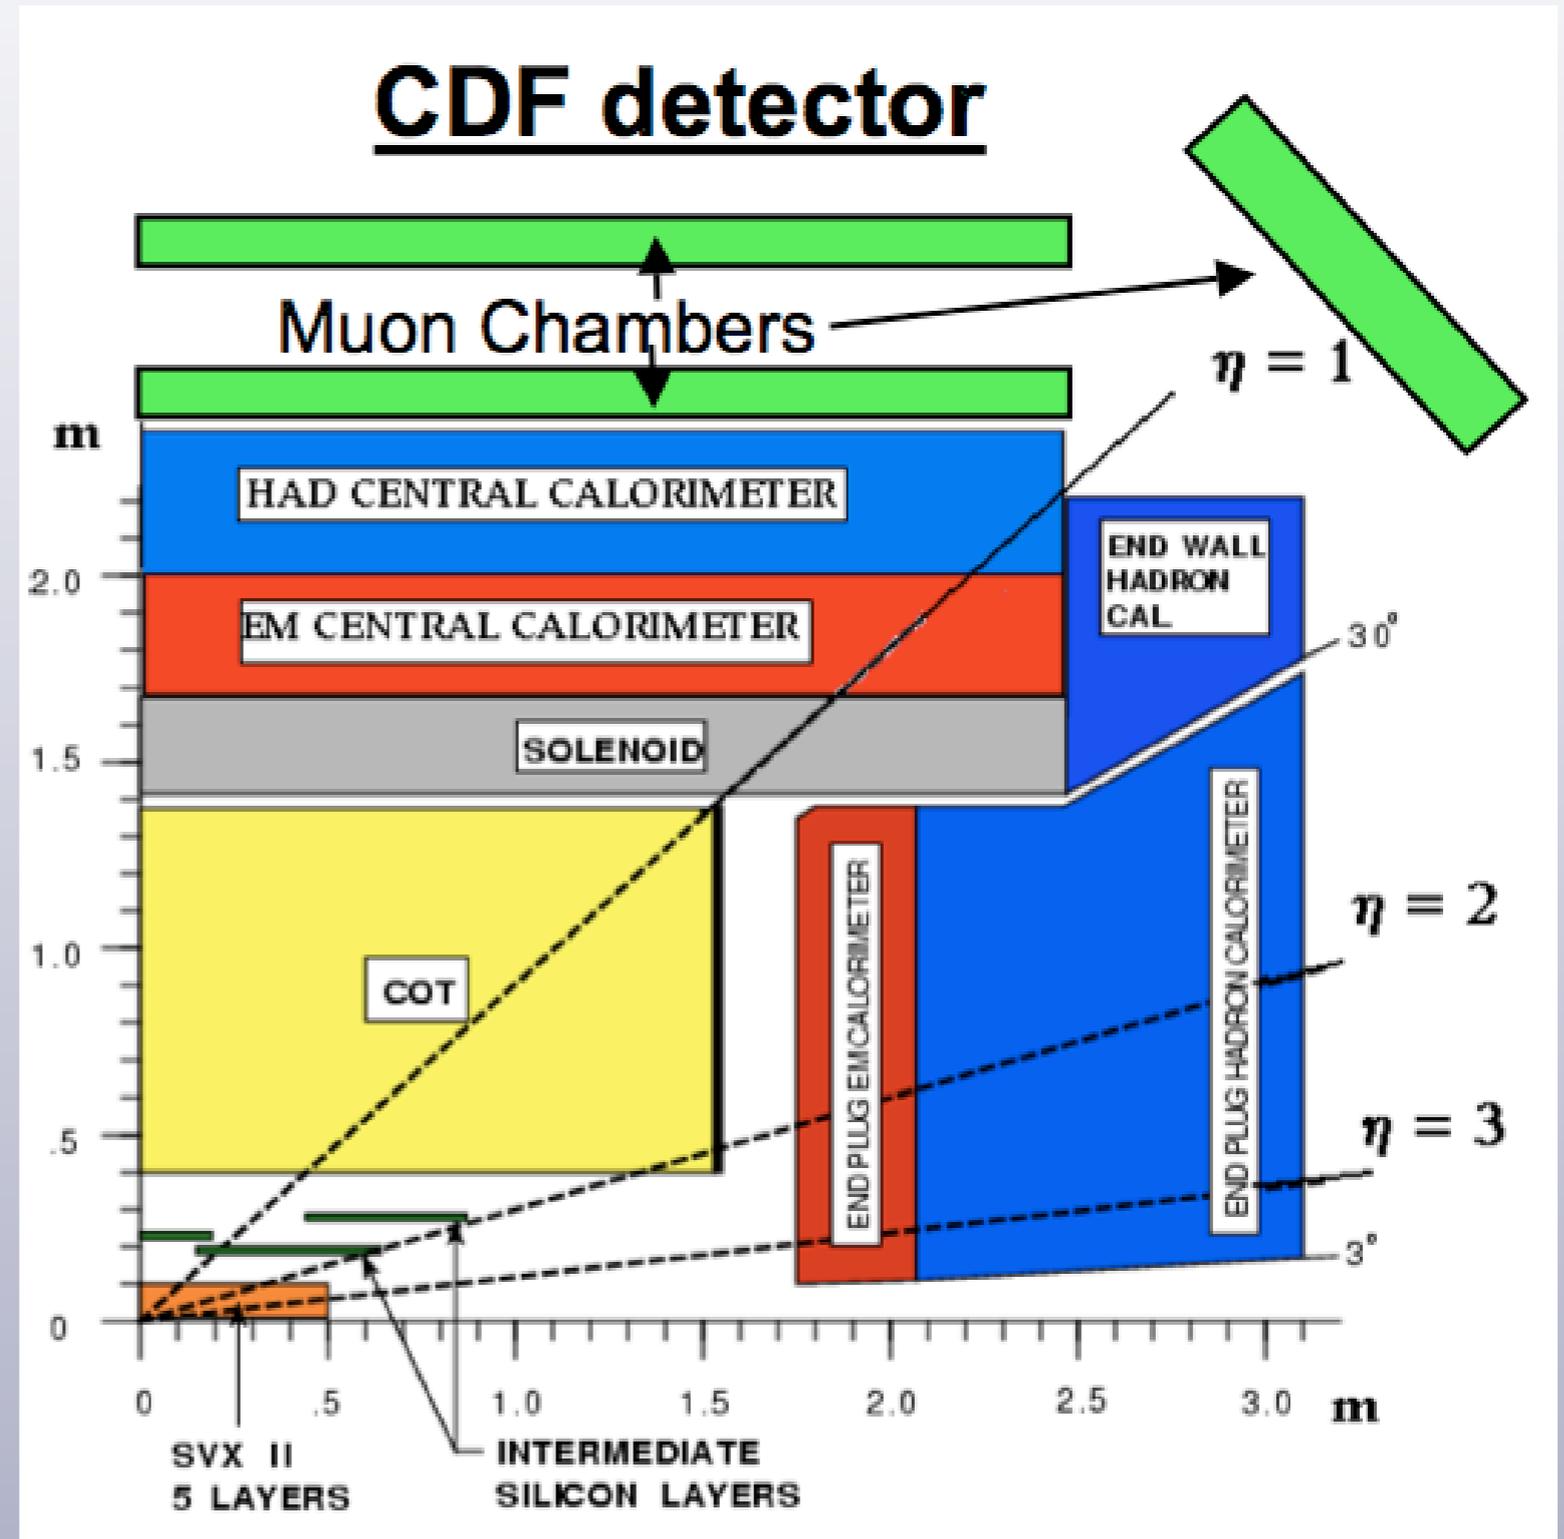

M_S Limit(TeV)	CDF	D0 (RunII)	D0(Run I+II)	LEP
$\lambda=+1$	0.96	1.22	1.28	1.1
$\lambda=-1$	0.99	1.10	1.16	1.2

Constraints from Non-Collider Experiments:

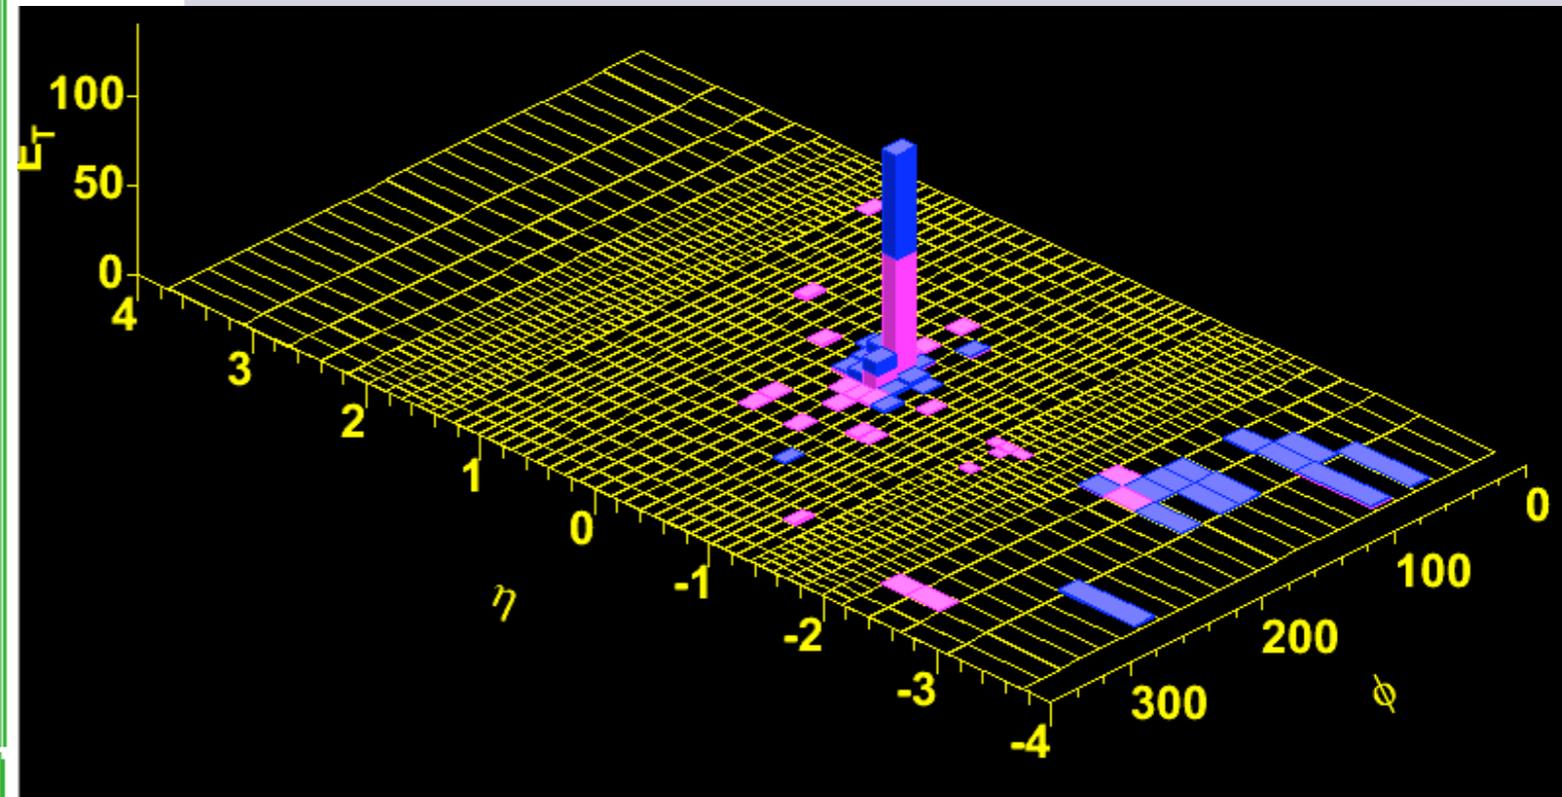

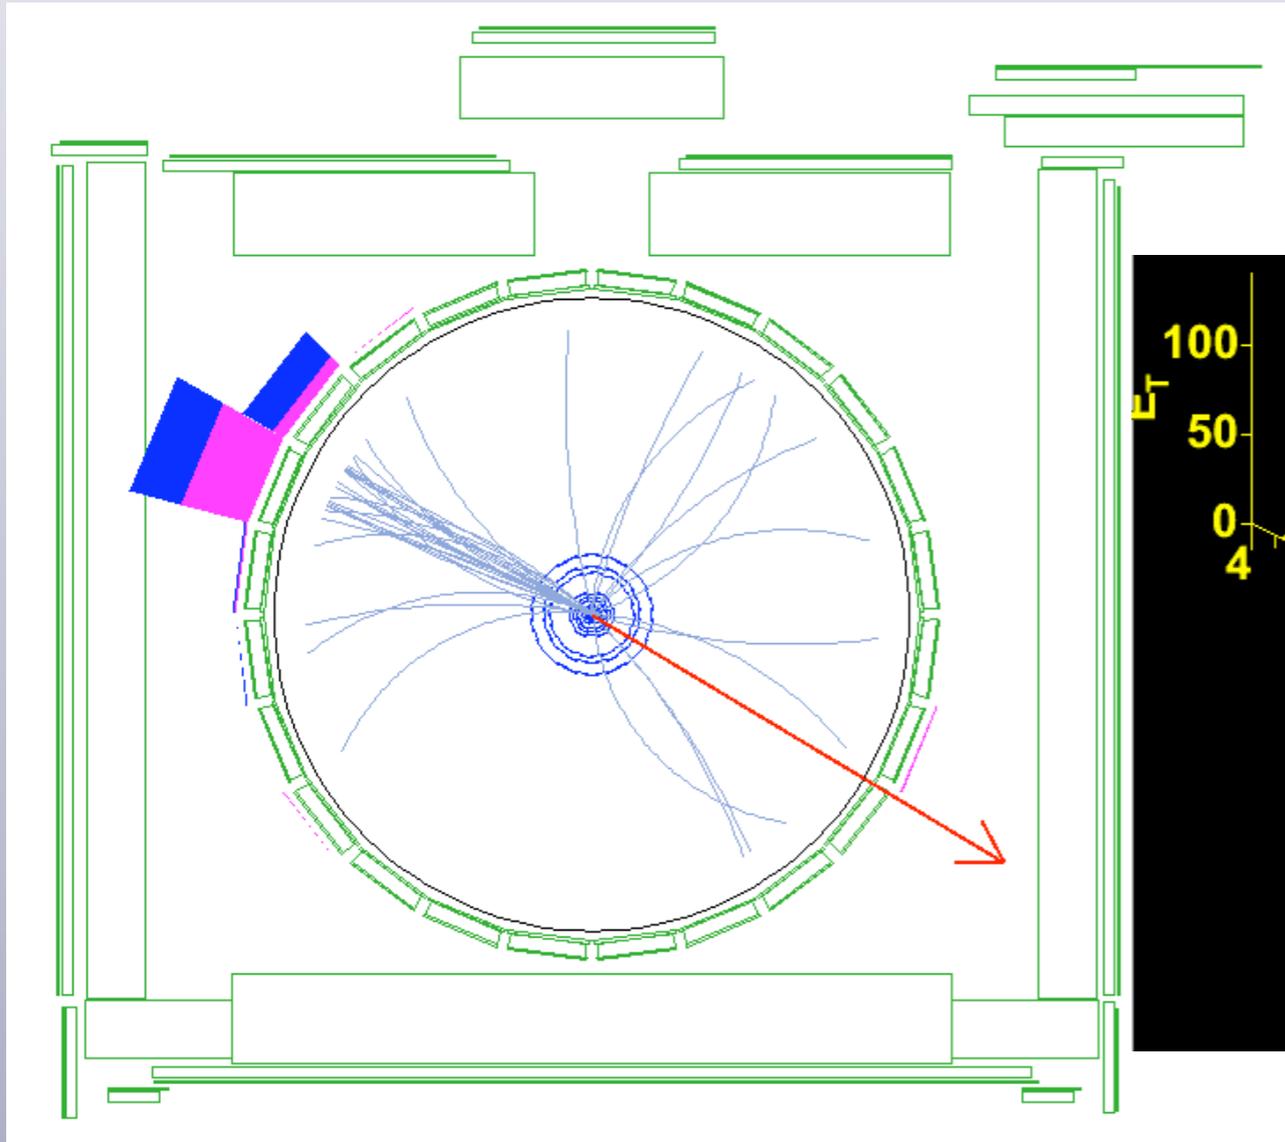

- Short Range Gravity Experiments:
 - $R < 130 \mu\text{m} (n=2) \Leftrightarrow M_D > 1.7 \text{ TeV}$
- Many cosmological constraints:
 - $M_D > 20-100 \text{ TeV} (n=2), M_D > 2-5 \text{ TeV} (n=3)$
 - But these depend on a lot of assumptions

- Most important upgrade for the monojet signal is the plug calorimeter
- Old gap between plug and forward at $|\eta|=2.4$ is gone

- What would the signal look like in the detector?
- All 3 graviton emission processes have same signature
- Graviton produces Missing E_T , quark/gluon creates a Jet

→ Monojet

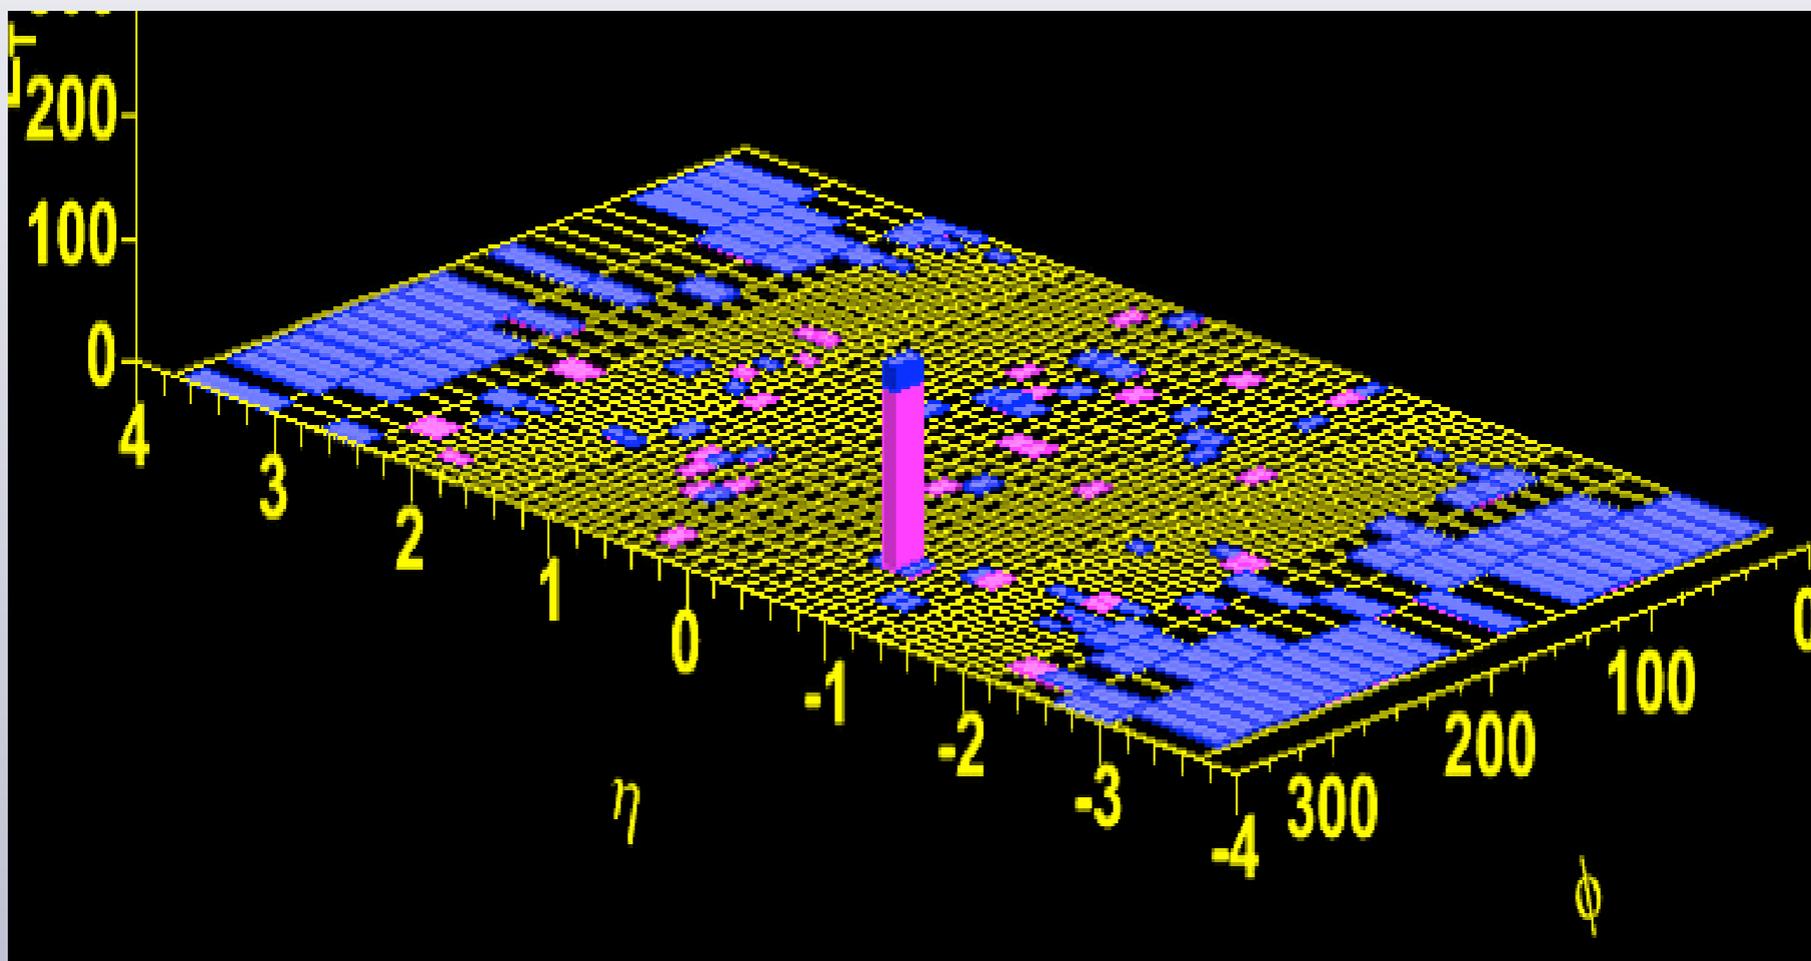

From Joe Lykken's talk “is particle physics ready for the LHC”

- missing energy + multijets among the most challenging searches at Tevatron Runs I and II

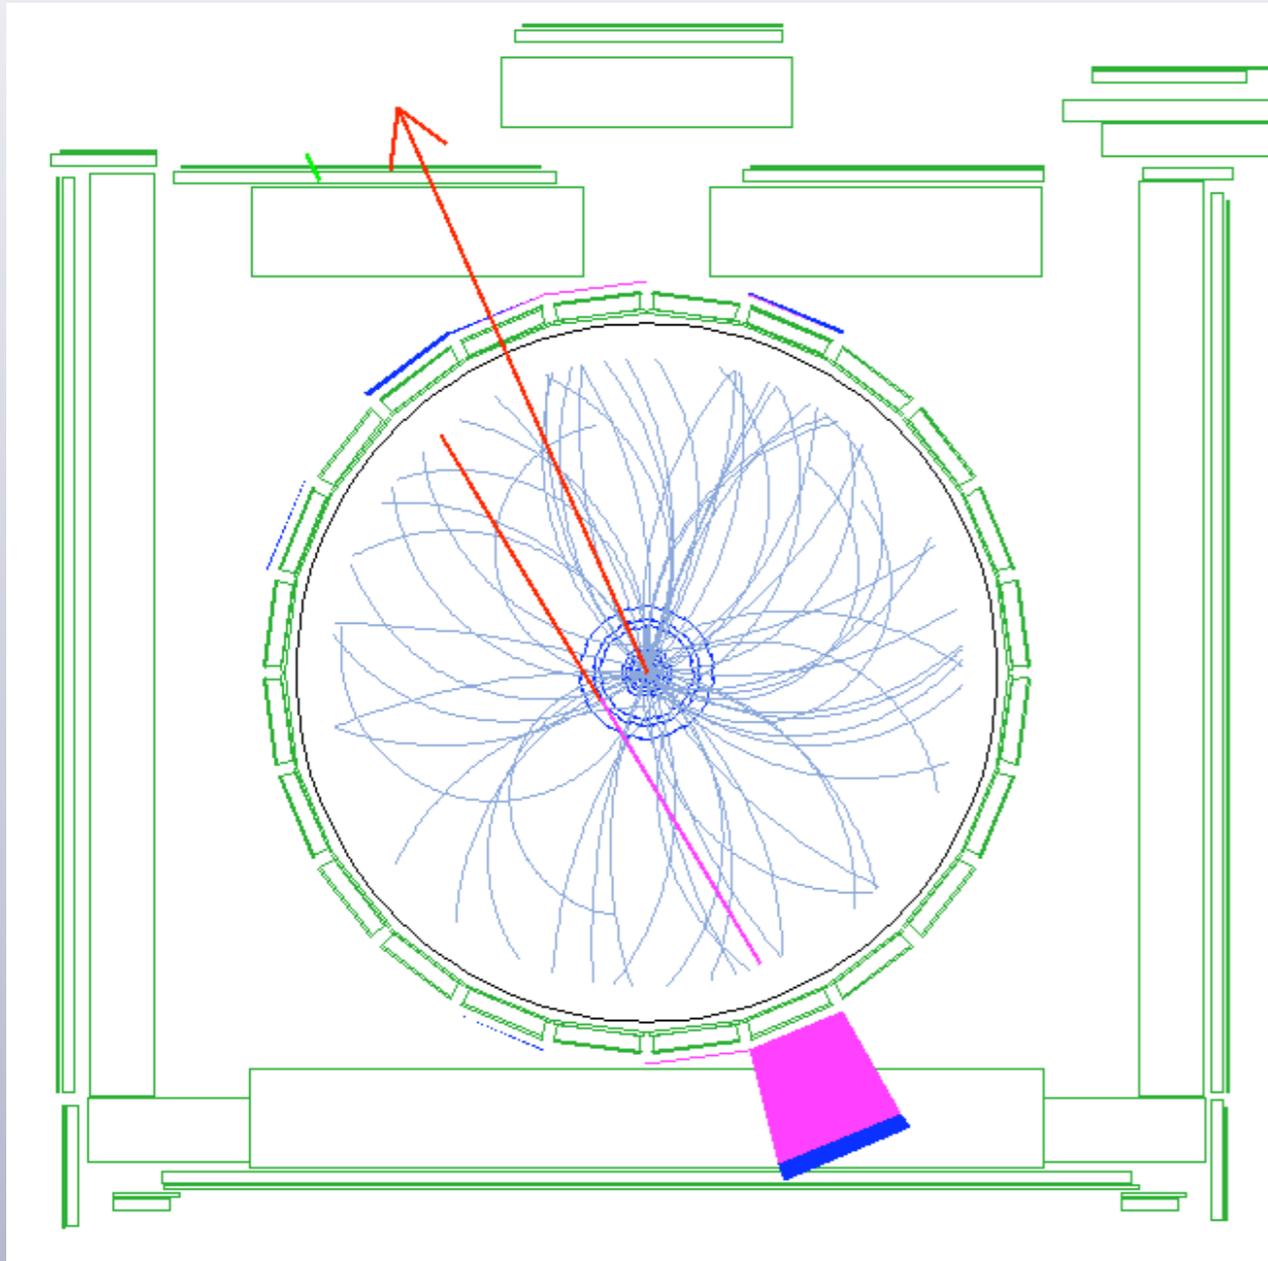

- monojet searches are even more difficult
- at the Tevatron, the *Run I* monojet analyses were not completed until 2003/2004
- but monojet searches are essential for probing extra dimensions

High E_T Jet and Missing E_T triggered events need to be checked carefully

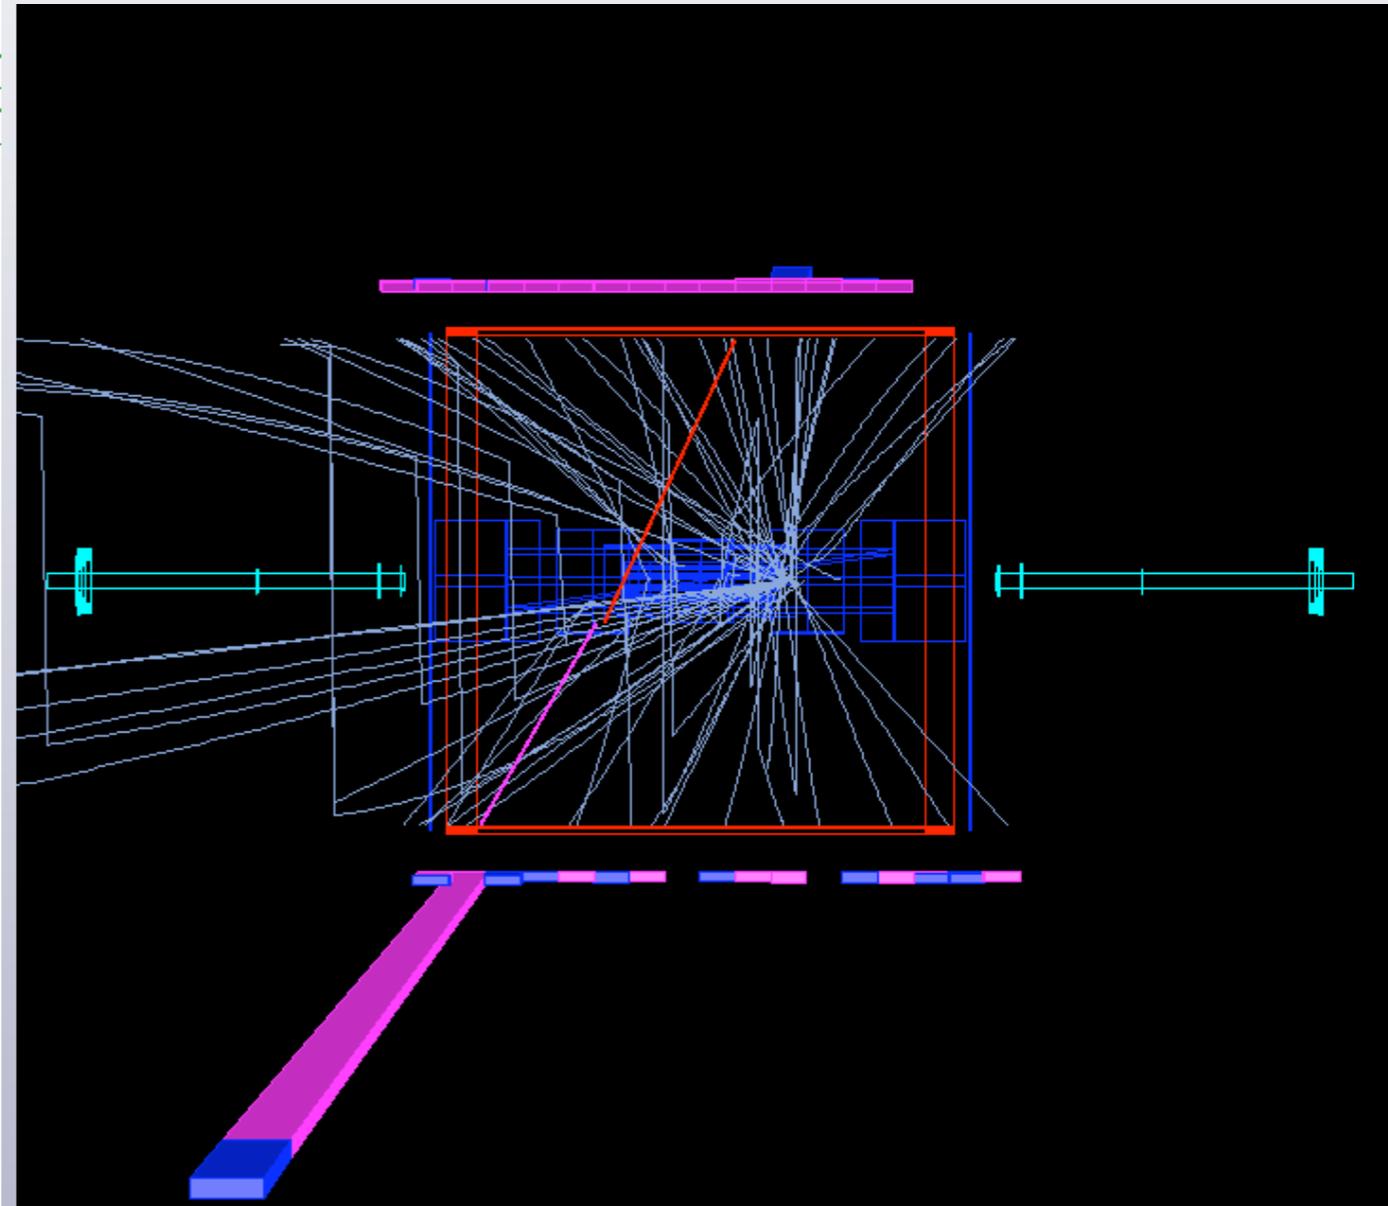

$$E_T(\text{Jet}) = 175 \text{ GeV}$$
$$\text{MET} = 170 \text{ GeV}$$

On closer inspection, it's a cosmic

COT View

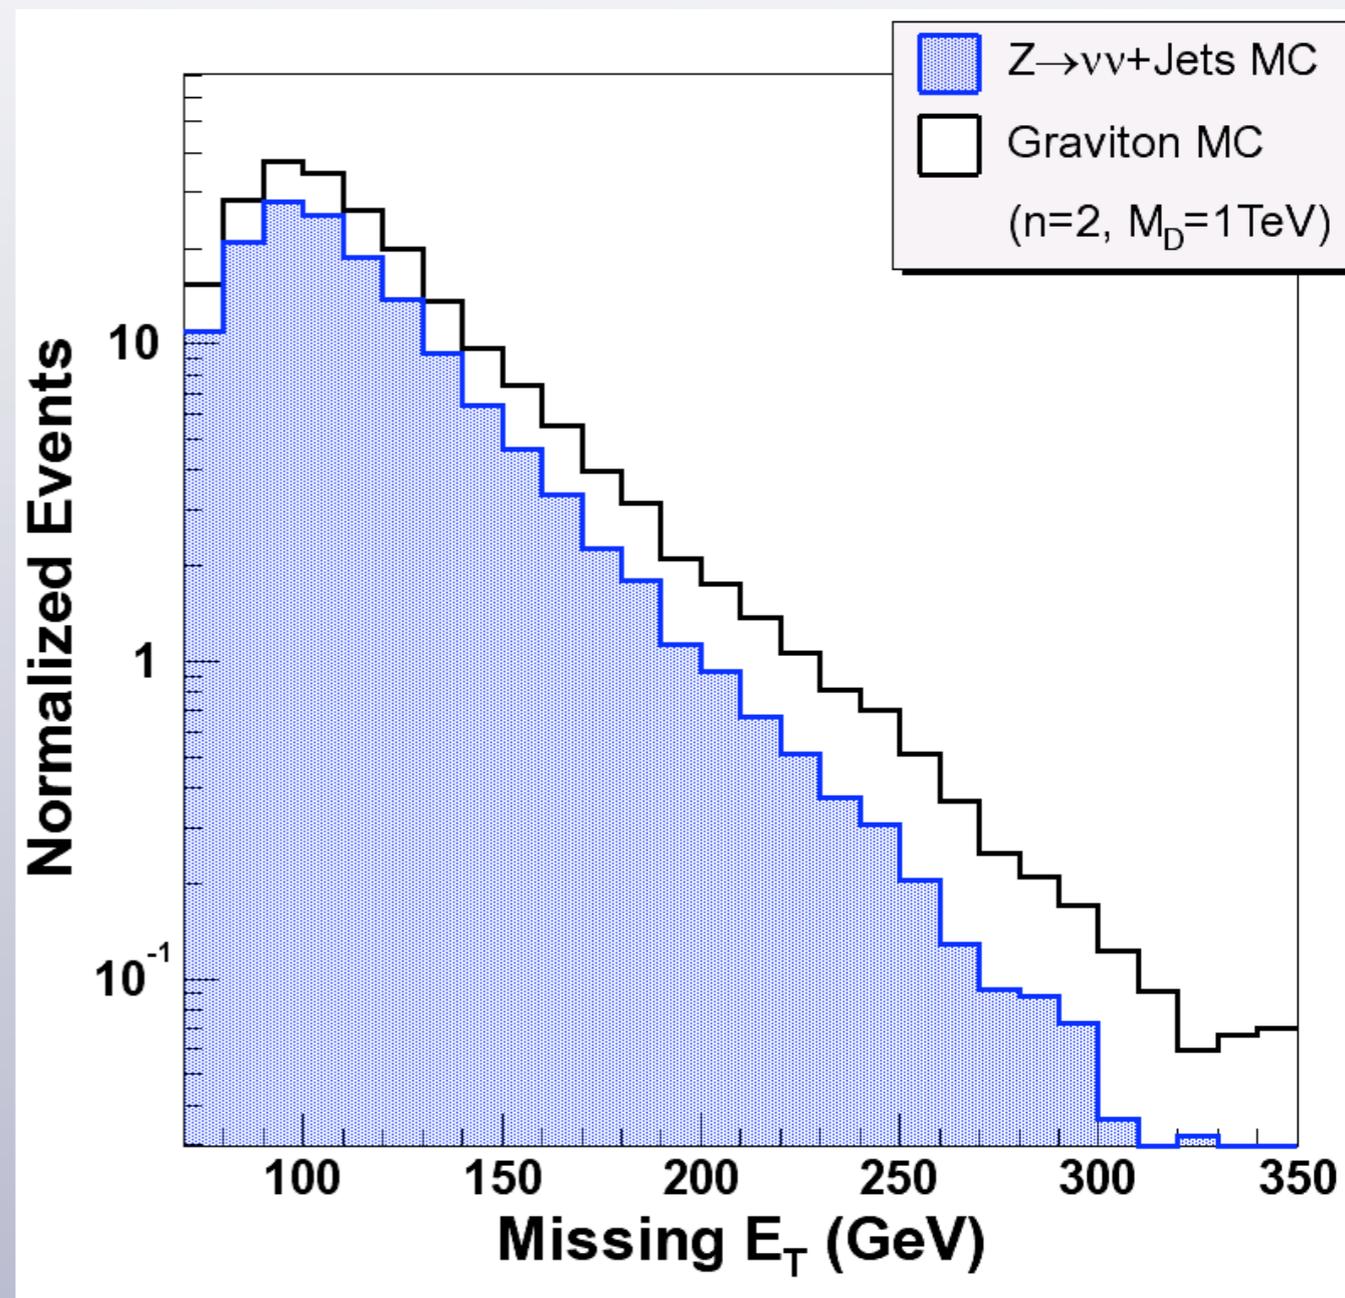

R-Z View

- $Z \rightarrow \nu\nu + \text{jets}$
- Irreducible - looks just like signal
- $W \rightarrow l\nu + \text{jets}$ ($l = \tau, \mu, e$)
- Real Missing $E_T \Rightarrow$ Reduce by vetoing leptons
- QCD
- Fake Missing E_T
- Non-Collision (cosmic, beam) Backgrounds

After removing all the non-collision backgrounds, graviton production will appear as a smooth excess over the SM backgrounds

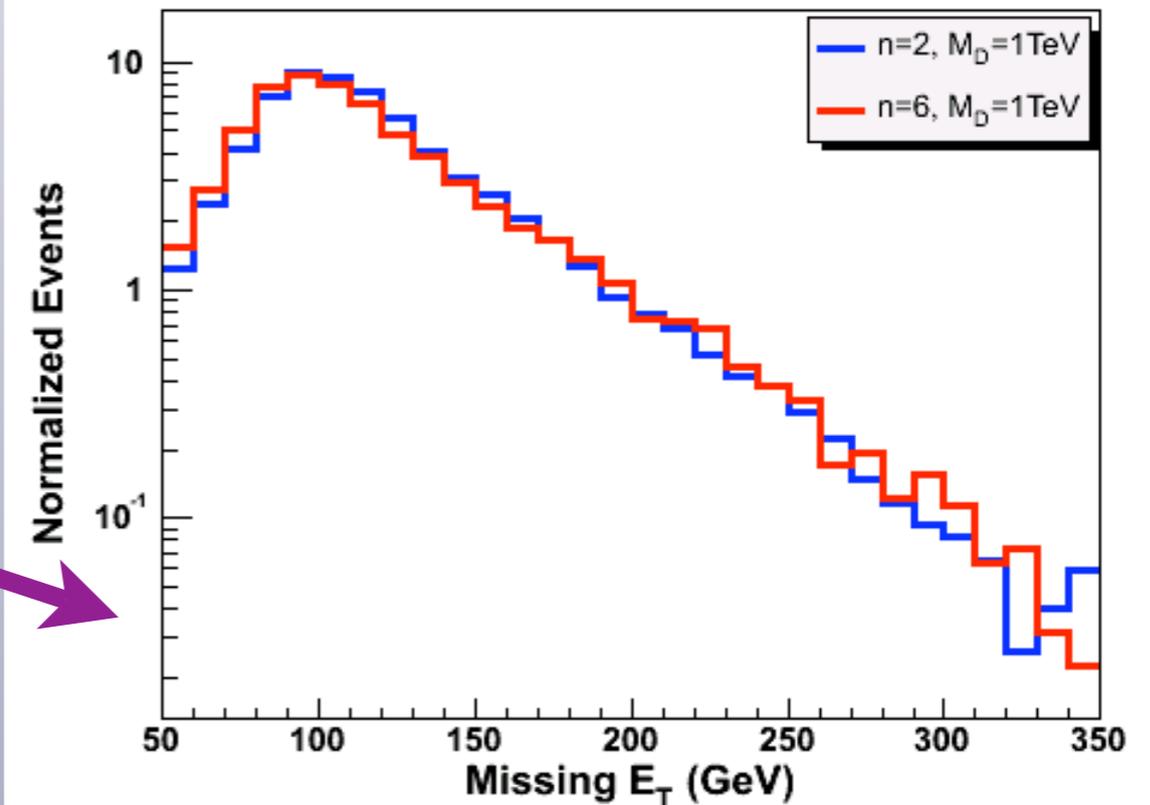

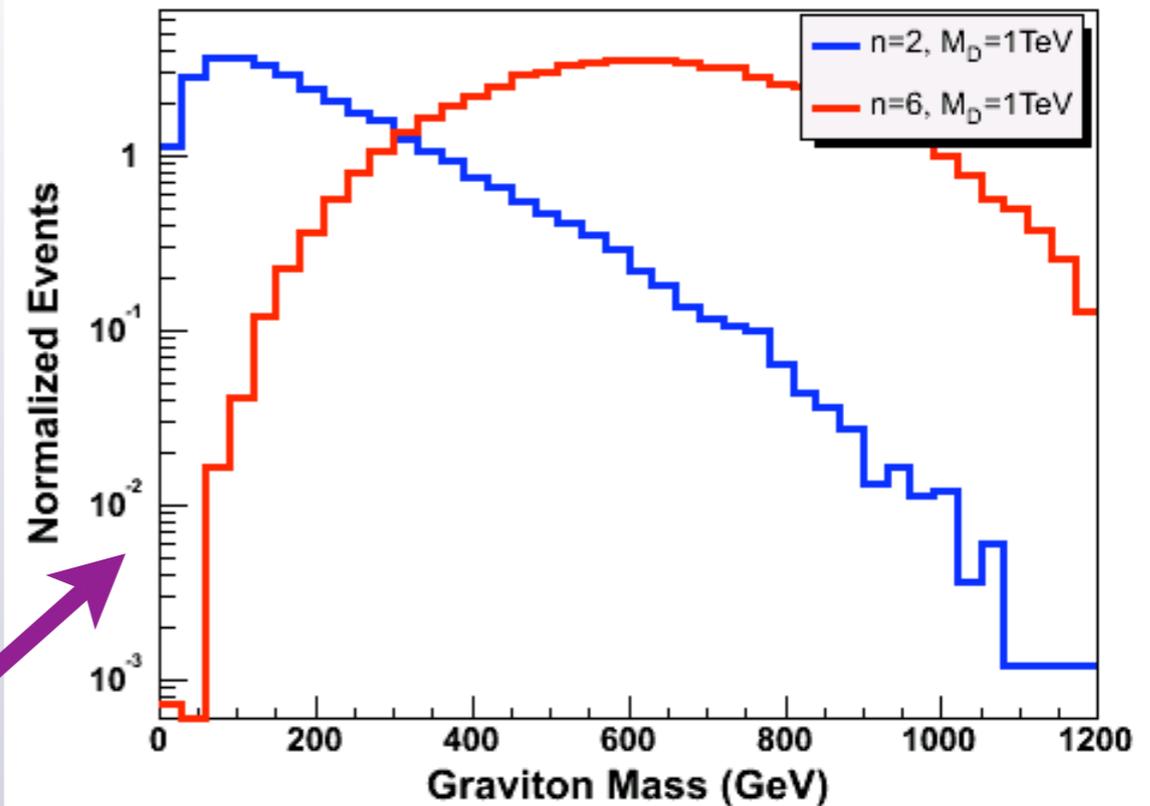

It would be difficult to determine n and M_D from an observed excess

The graviton mass spectra differ with n , but the P_T of the graviton (observed as Missing E_T) is almost identical

1. Semi-model independent analysis

- Cuts not uniquely optimized for graviton signature
- Use data from highest E_T Jet trigger
- general optimization of cuts to remove electroweak and fake MET backgrounds

2. As much as possible, estimate backgrounds from data

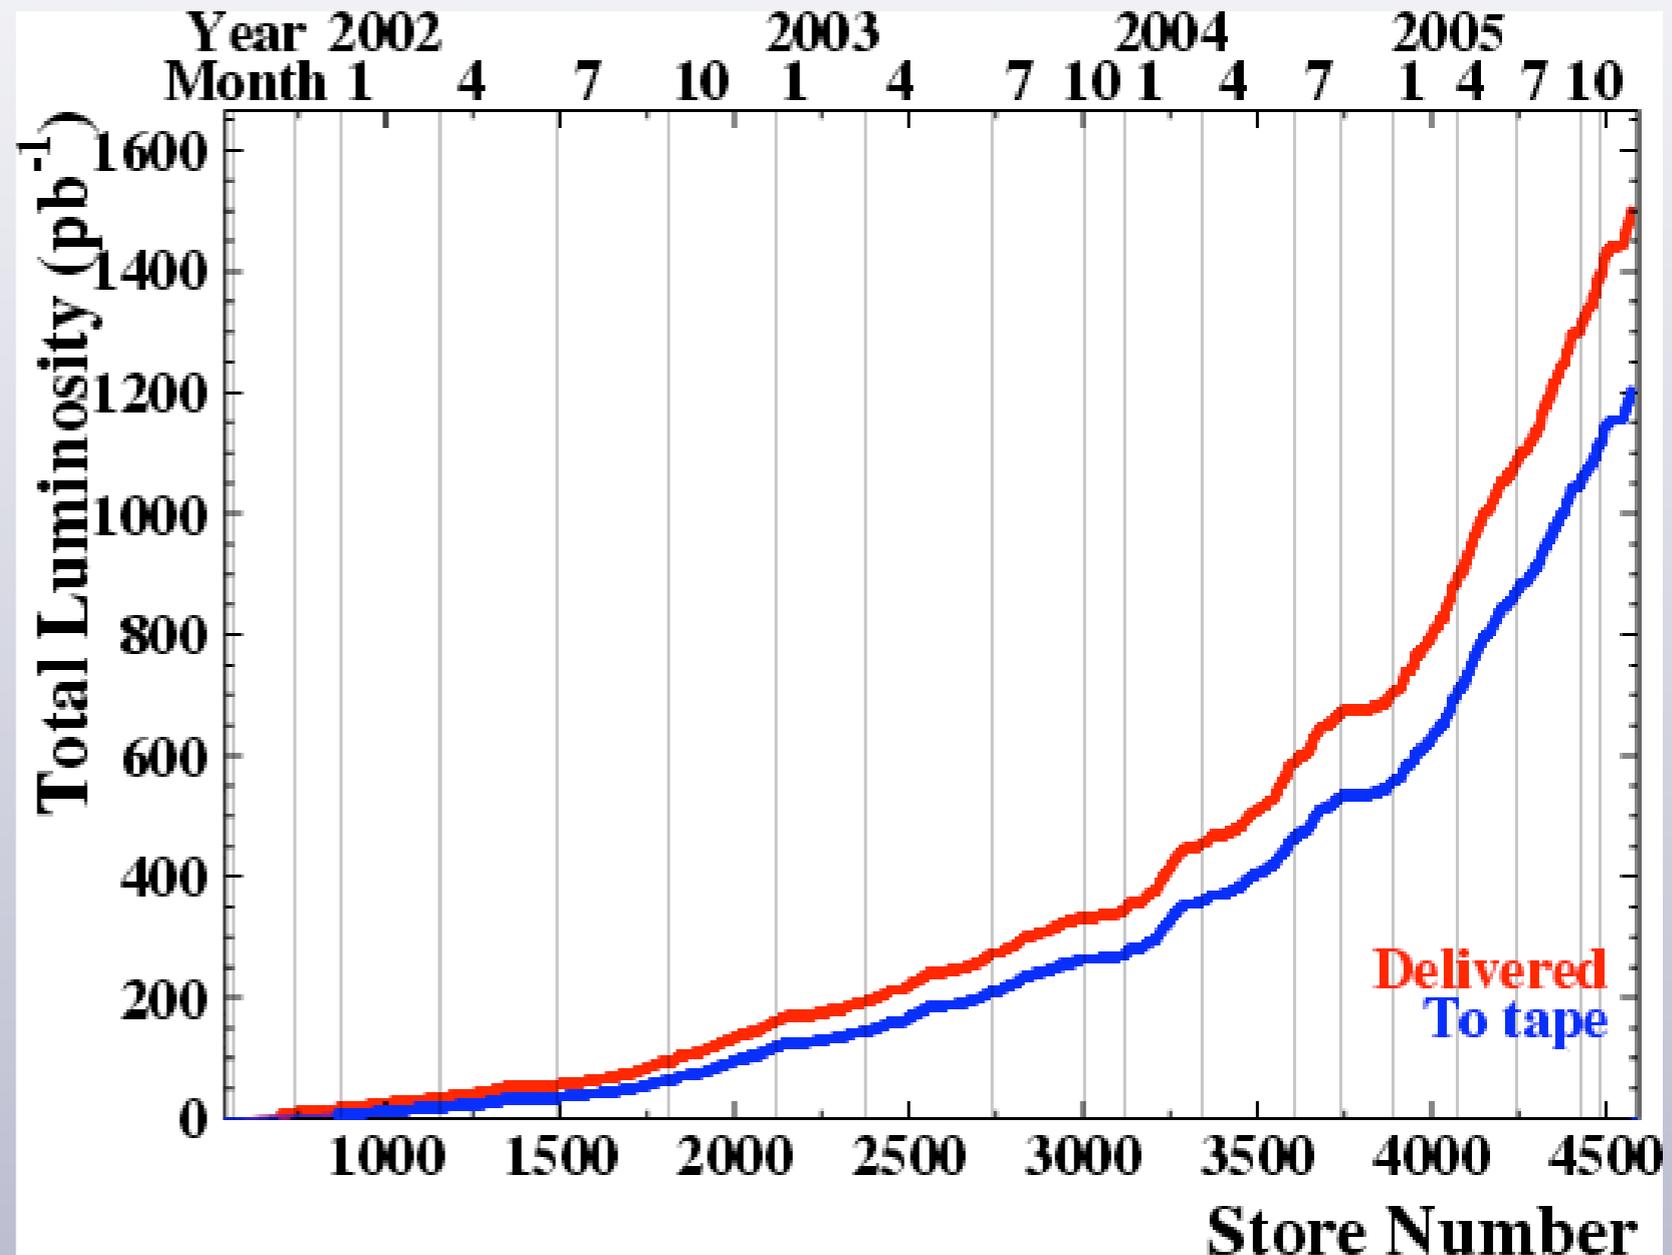

- e.g. use $Z \rightarrow ll + \text{jets}$ and $W \rightarrow lv + \text{jets}$ to estimate electroweak backgrounds

Data Samples

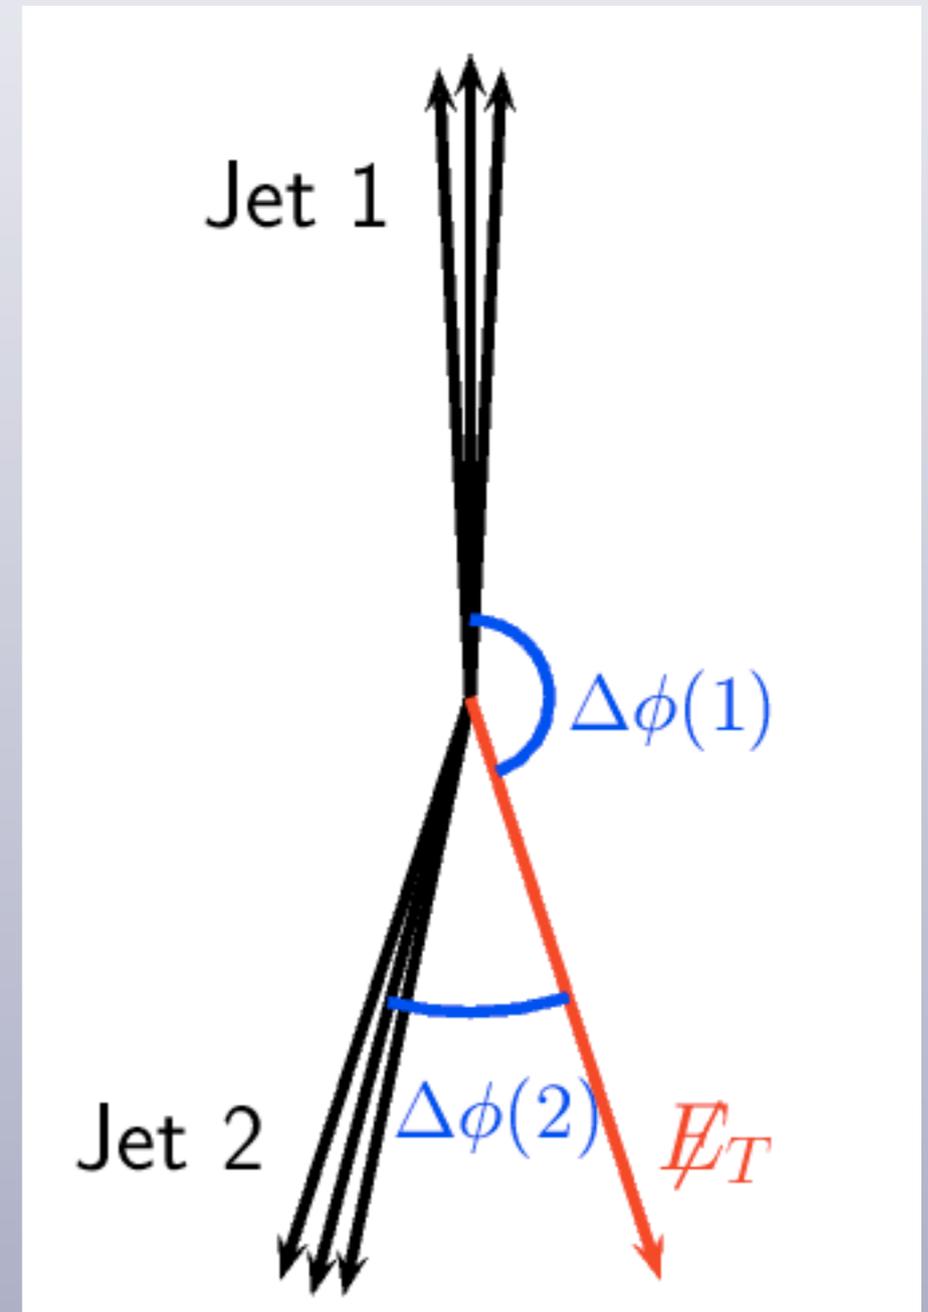

- Most samples used in analyses presented today use physics data taken prior to shutdown in Aug 2004
- Luminosity analyzed is $\sim 370 \text{ pb}^{-1}$

- Using High E_T Jet Trigger
 - Same non-collision backgrounds as Missing E_T trigger
 - Need initial event cleanup
 - Vertex reconstructed with >5 tracks, $|z| < 60\text{cm}$
 - Event EM Fraction > 0.1
 - Leading jet central, Jet charge fraction > 0.1
 - Veto events with jets pointing to cracks

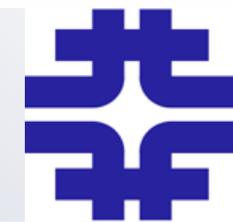

- Require 1 High E_T jet ($E_T > 150$ GeV)
- Allow soft second jet ($E_T < 60$ GeV), likely from radiation
- Missing $E_T > 120$ GeV

- Veto leptons to reduce EWK backgrounds
- Isolated tracks $P_T > 10$ GeV/c
- Jets with EM Fraction > 0.9
- Reduce fake Missing E_T background by requiring $\Delta\Phi(\text{MET-Jet}) > 0.3$

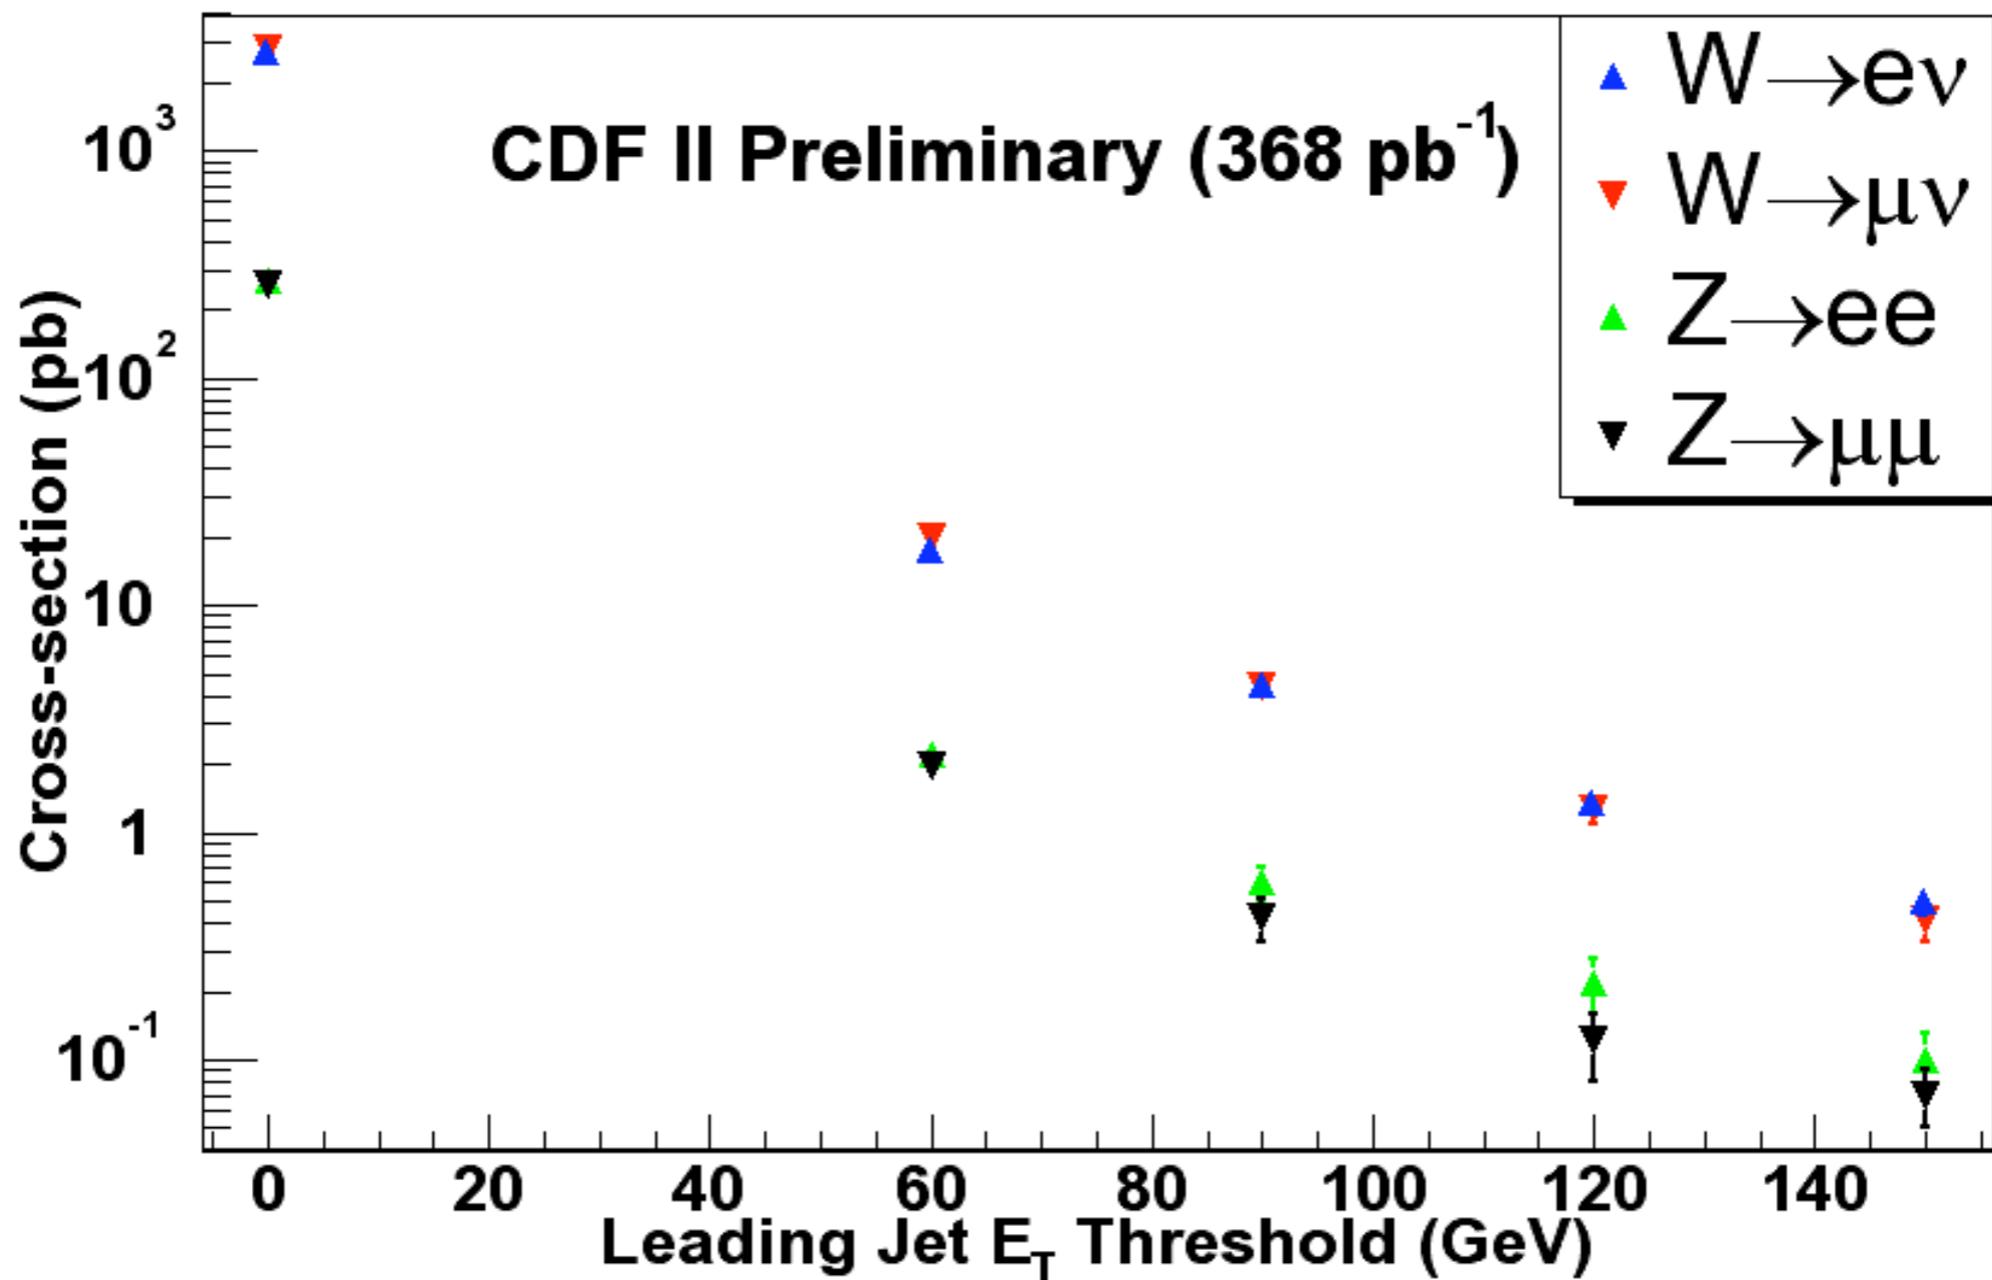

Electroweak Backgrounds

- Dominant background is $Z \rightarrow \nu\nu + \text{jets}$
- Large integrated luminosity in RunII means backgrounds can be estimated **from data** rather than from MC
- Use $Z \rightarrow ee + \text{jets}$ and $Z \rightarrow \mu\mu + \text{jets}$ events, with leptons removed to model $Z \rightarrow \nu\nu + \text{jets}$
- Can also estimate $Z \rightarrow \nu\nu + \text{jets}$ background from higher statistics $W \rightarrow lv + \text{jets}$ samples, using theoretical prediction for $R_{W/Z} = \sigma(W)/\sigma(Z)$

- Measure $\sigma(W)$ and $\sigma(Z)$ for inclusive and for a range of leading jet cuts (60, 90, 120, 150 GeV)
- Use standard W, Z selection to take advantage of known efficiencies, scale factors, etc.
- Check inclusive cross-section against published results
- Higher statistics at lower jet E_T cuts allow statistically significant comparisons
- Estimate $Z \rightarrow \nu\nu + \text{jets}$ with:
 - $\sigma(Z \rightarrow \nu\nu + \text{jets}) = 6 \times \sigma(Z \rightarrow ll + \text{jets})$
 - $\sigma(Z \rightarrow \nu\nu + \text{jets}) = 6 \times \sigma(W \rightarrow lv + \text{jets}) / R_{W/Z}$

$$\sigma(W \rightarrow e\nu) = 2727 \pm 46 \text{ pb}$$

$$\sigma(Z \rightarrow ee) = 268 \pm 5 \text{ pb}$$

$$\sigma(W \rightarrow \mu\nu) = 2778 \pm 31 \text{ pb}$$

$$\sigma(Z \rightarrow \mu\mu) = 258 \pm 3 \text{ pb}$$

Use MCFM (MonteCarlo for FeMtobarn processes) to calculate $R_{W/Z}$

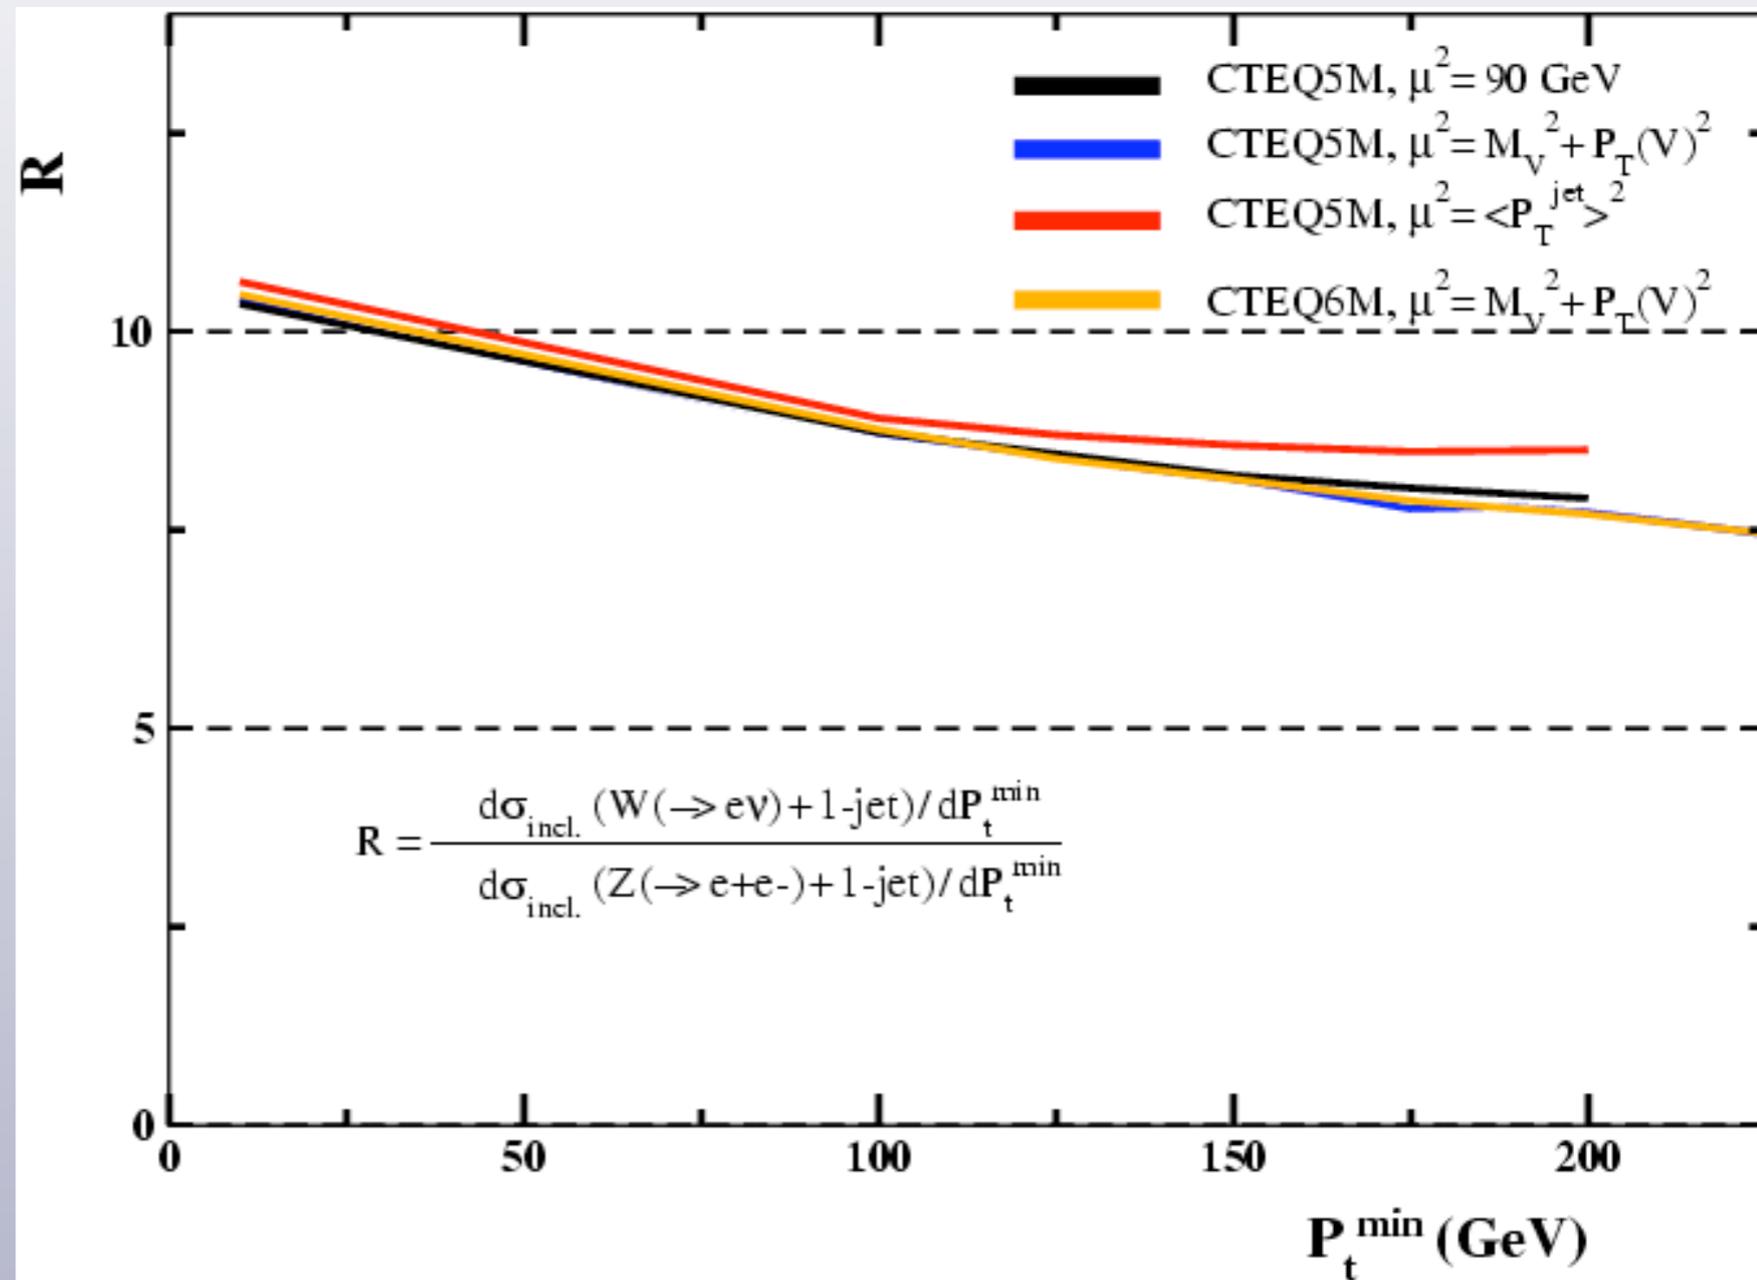

$R_{W/Z} = 8.15 \pm 0.40$
($P_T^{\min} = 150$ GeV)

Uncertainties:

4% renorm.
scale

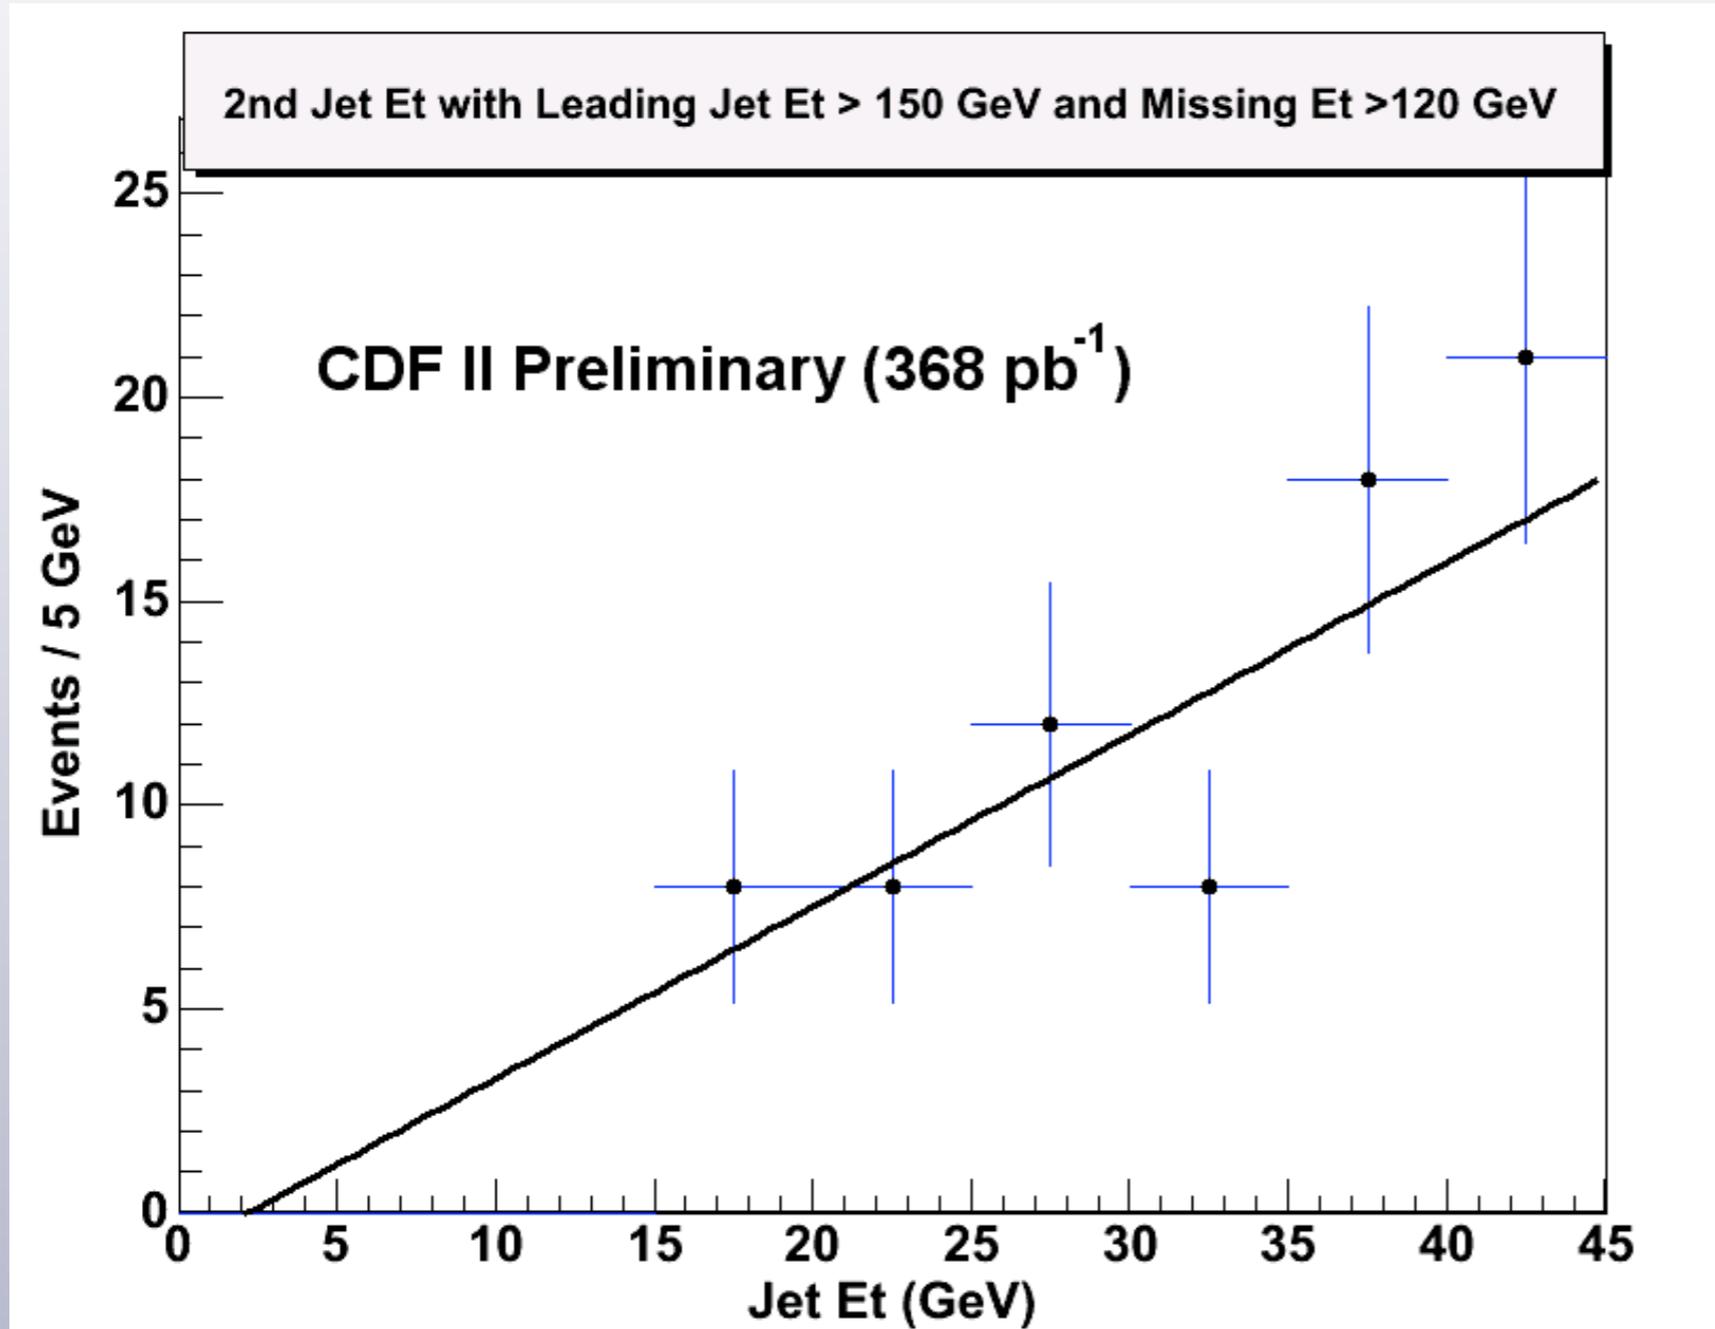

1% PDF

2% JES

- Estimates of $Z \rightarrow \nu\nu + \text{jets}$
 - From $\sigma(Z \rightarrow ll + \text{jets})$ estimate 177 ± 44 events
 - From $\sigma(W \rightarrow l\nu + \text{jets})$ estimate 125 ± 15 events
 - Combined estimate: 130 ± 14 events
- Same samples used to estimate other EWK backgrounds:
 - $W \rightarrow \tau\nu$: 60 ± 7
 - $W \rightarrow \mu\nu$: 36 ± 4
 - $W \rightarrow e\nu$: 17 ± 2
 - $Z \rightarrow ll$: 3 ± 1

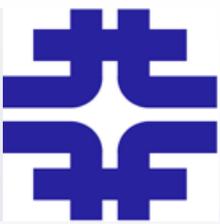

- Dominant source of QCD background is dijet events where 2nd jet is lost
- ~15% of QCD background comes from 3-jet events (ratio determined from MC)
- Use data to estimate background
 - Select dijets where 2nd jet close in ϕ to MET
 - Extrapolate $E_T(\text{Jet2})$ distribution to region where jet falls below threshold and is lost

- Extrapolation yields **13 dijet** events
- **2 additional** events from 3-jet events
- Total QCD background: **15 ± 10** events

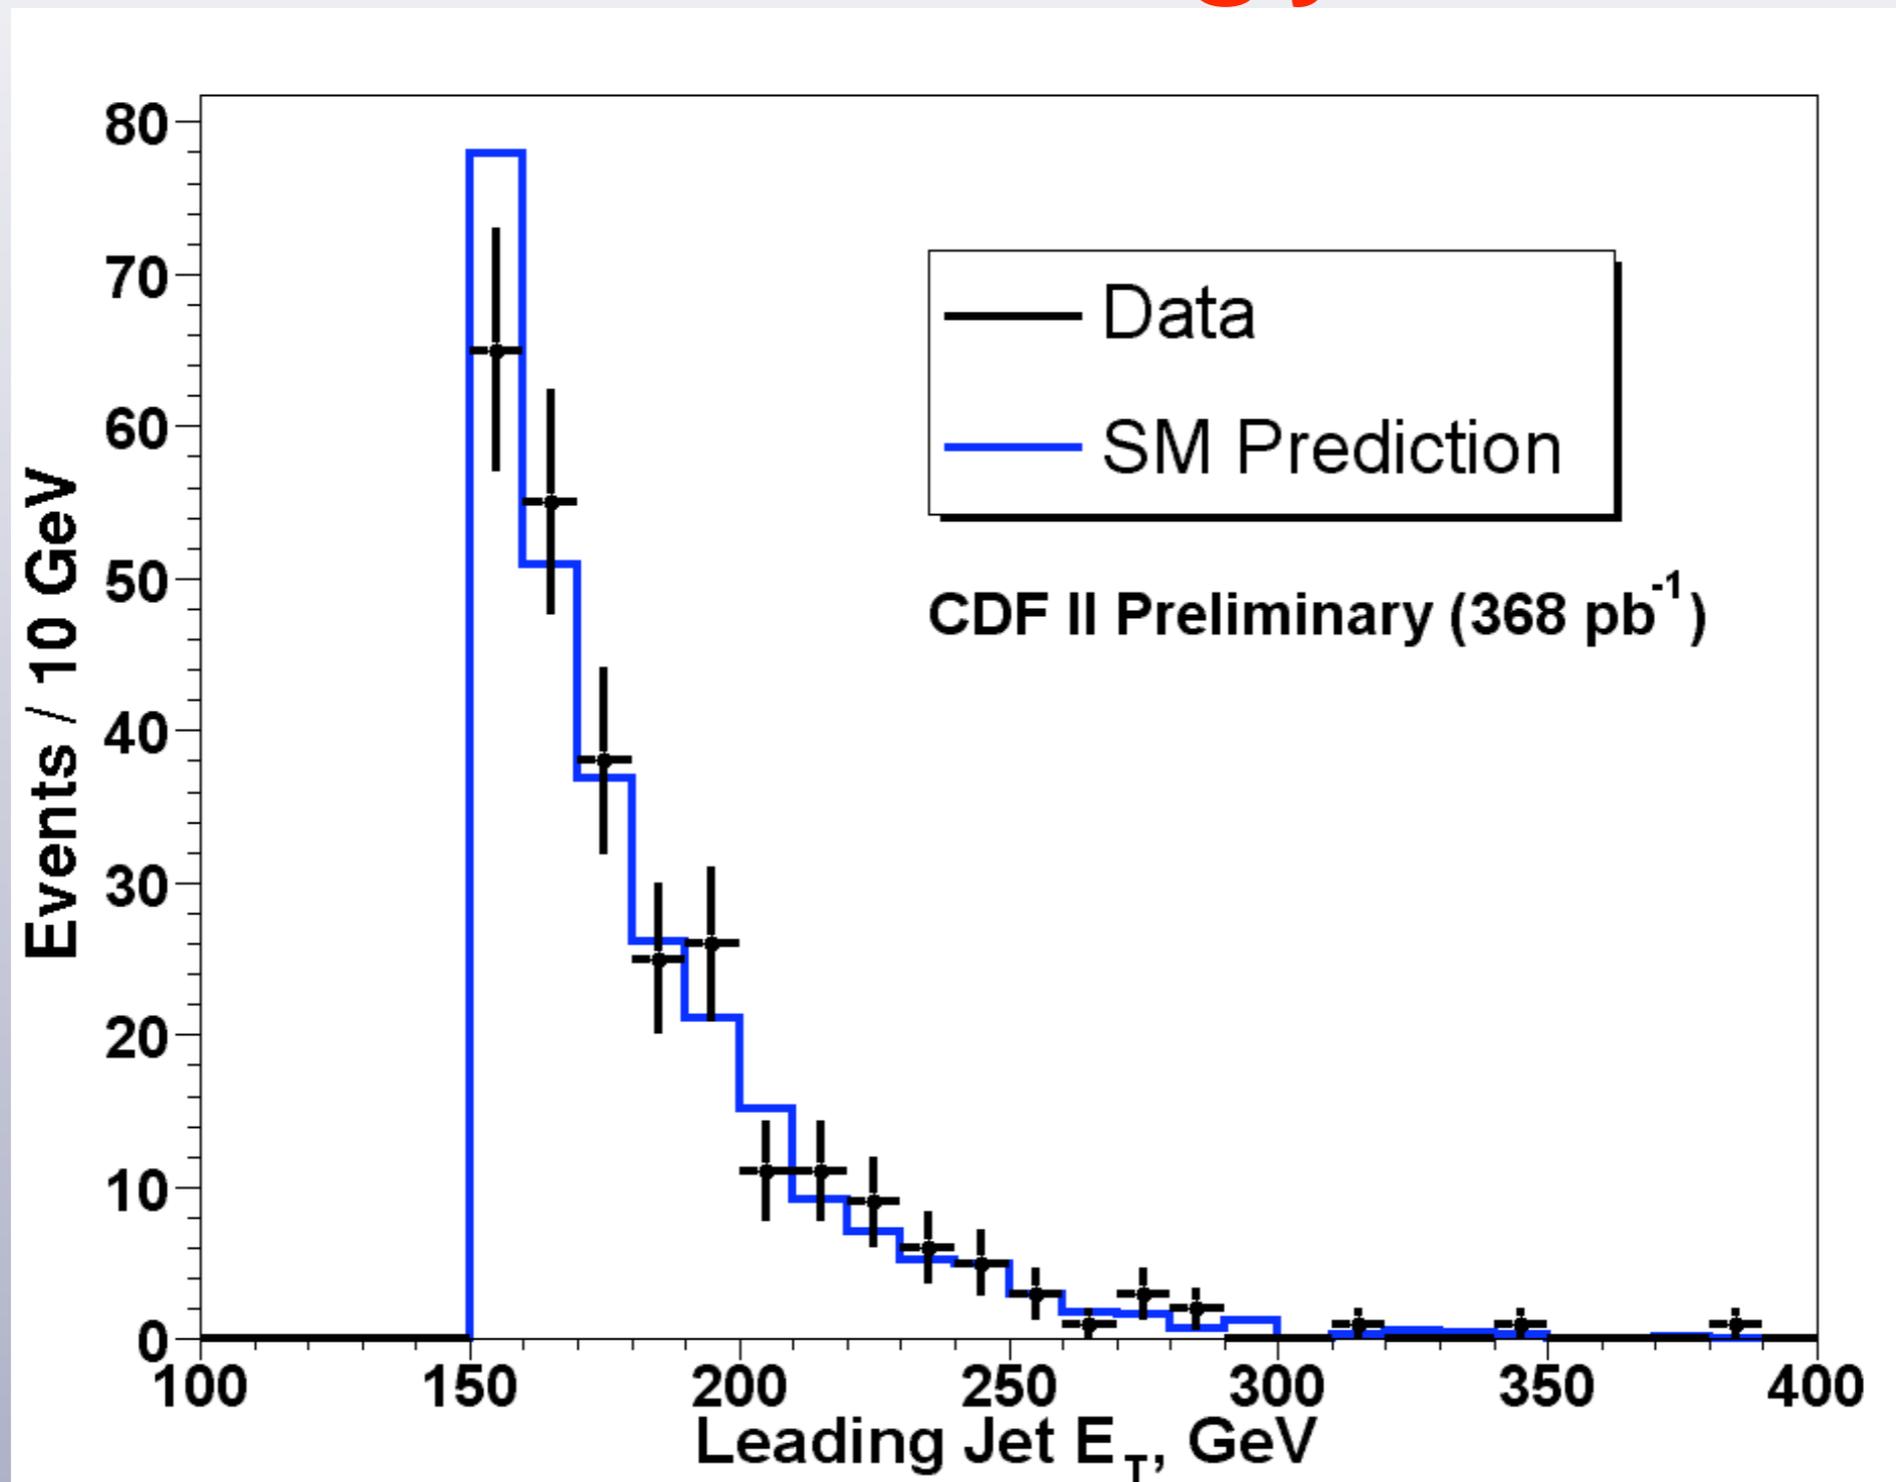

Summary of Backgrounds

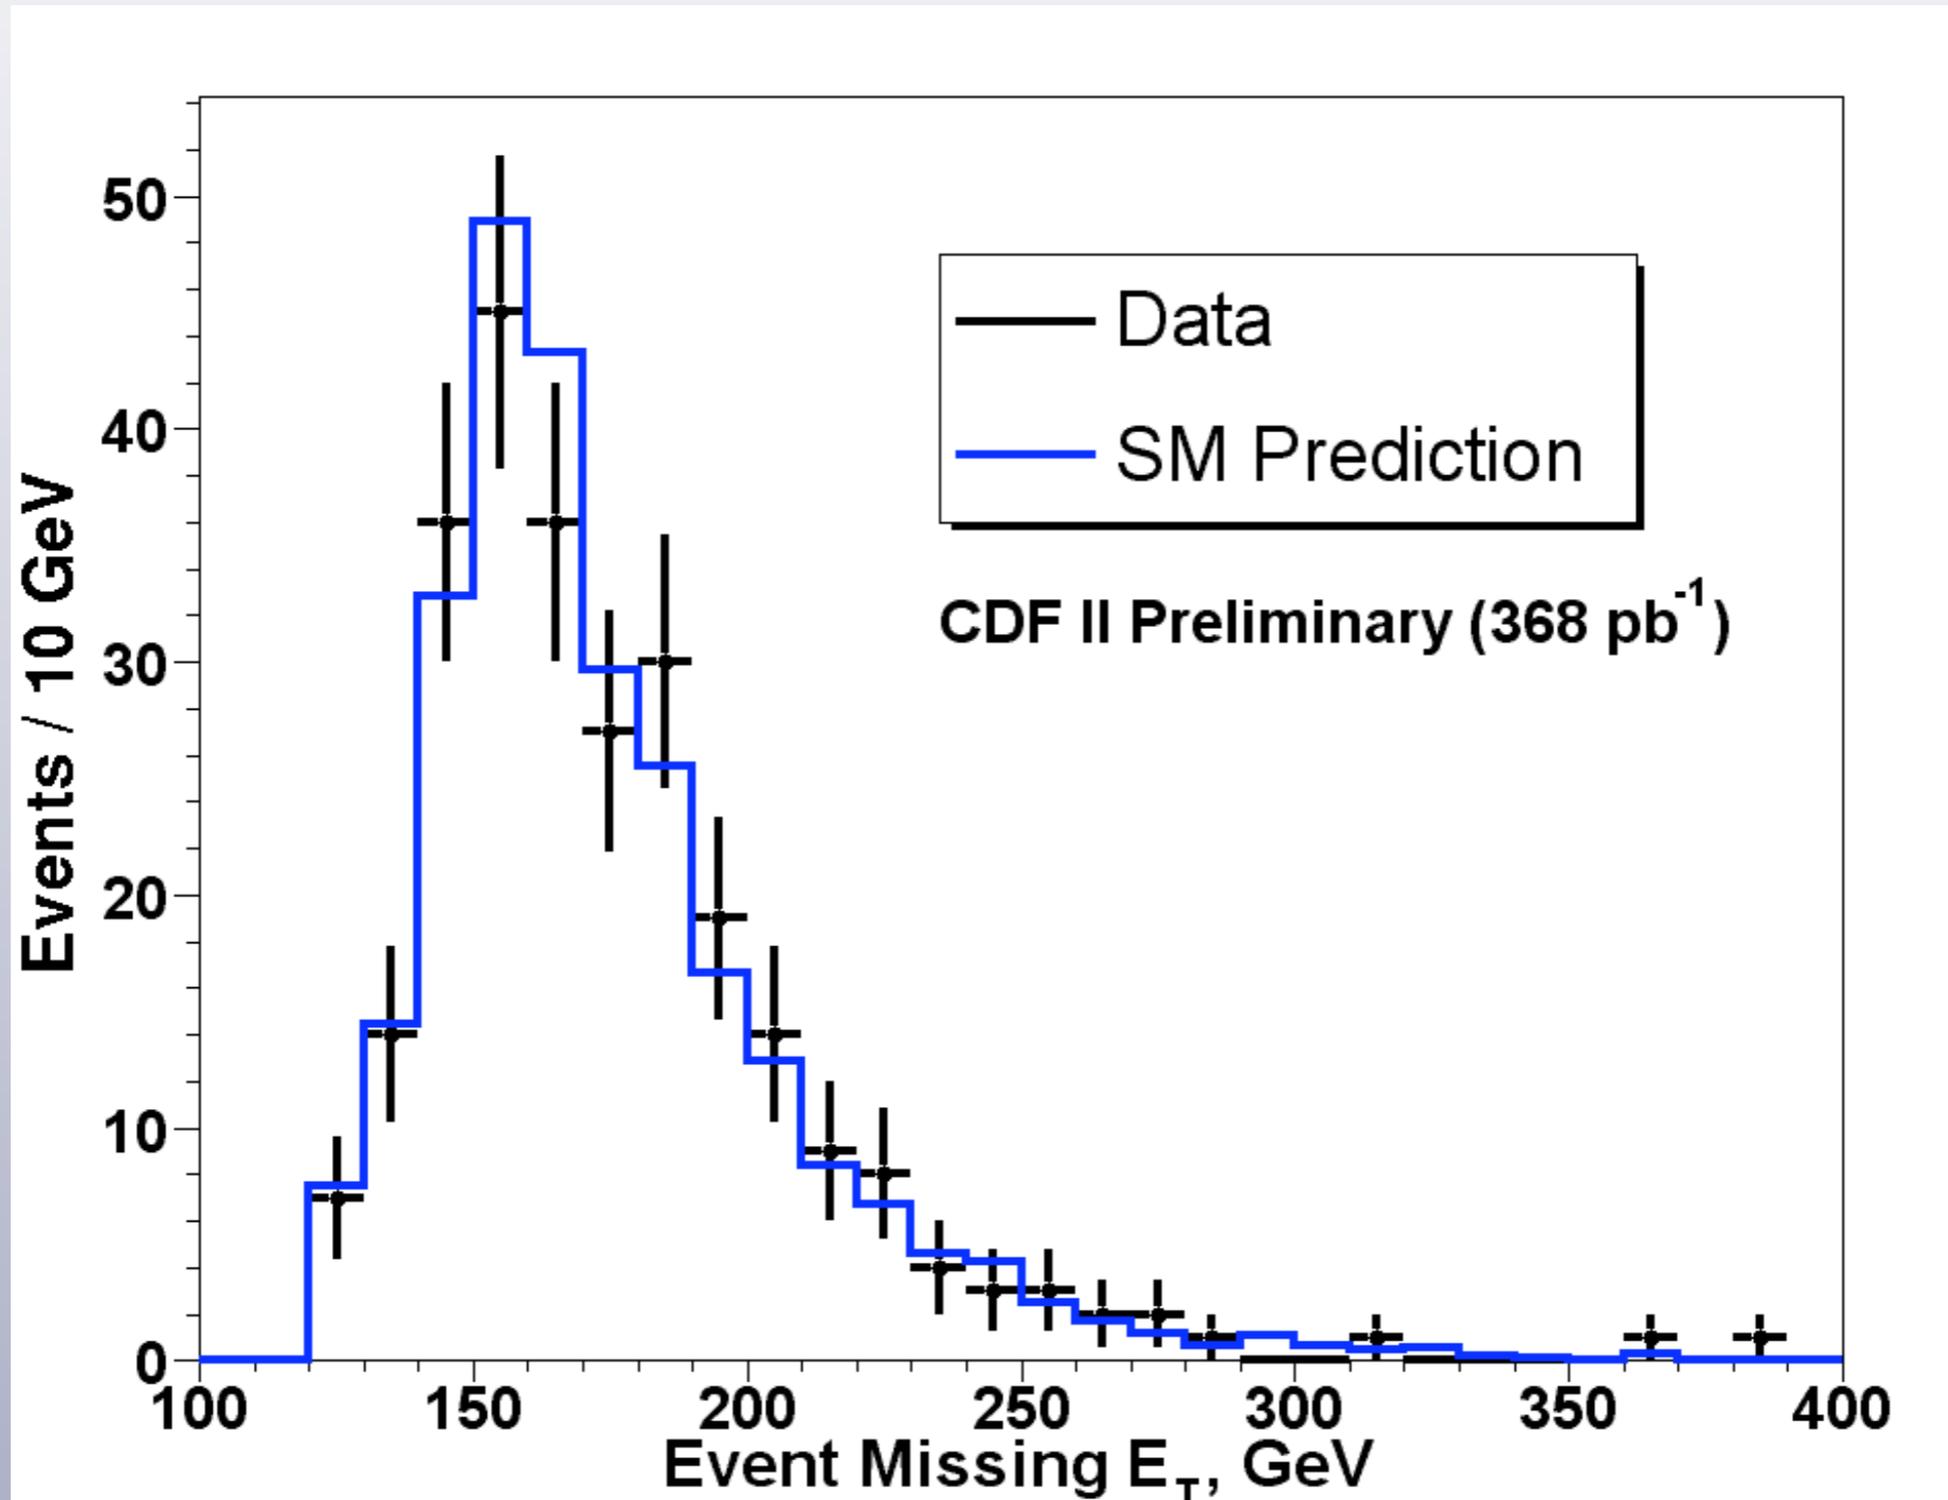

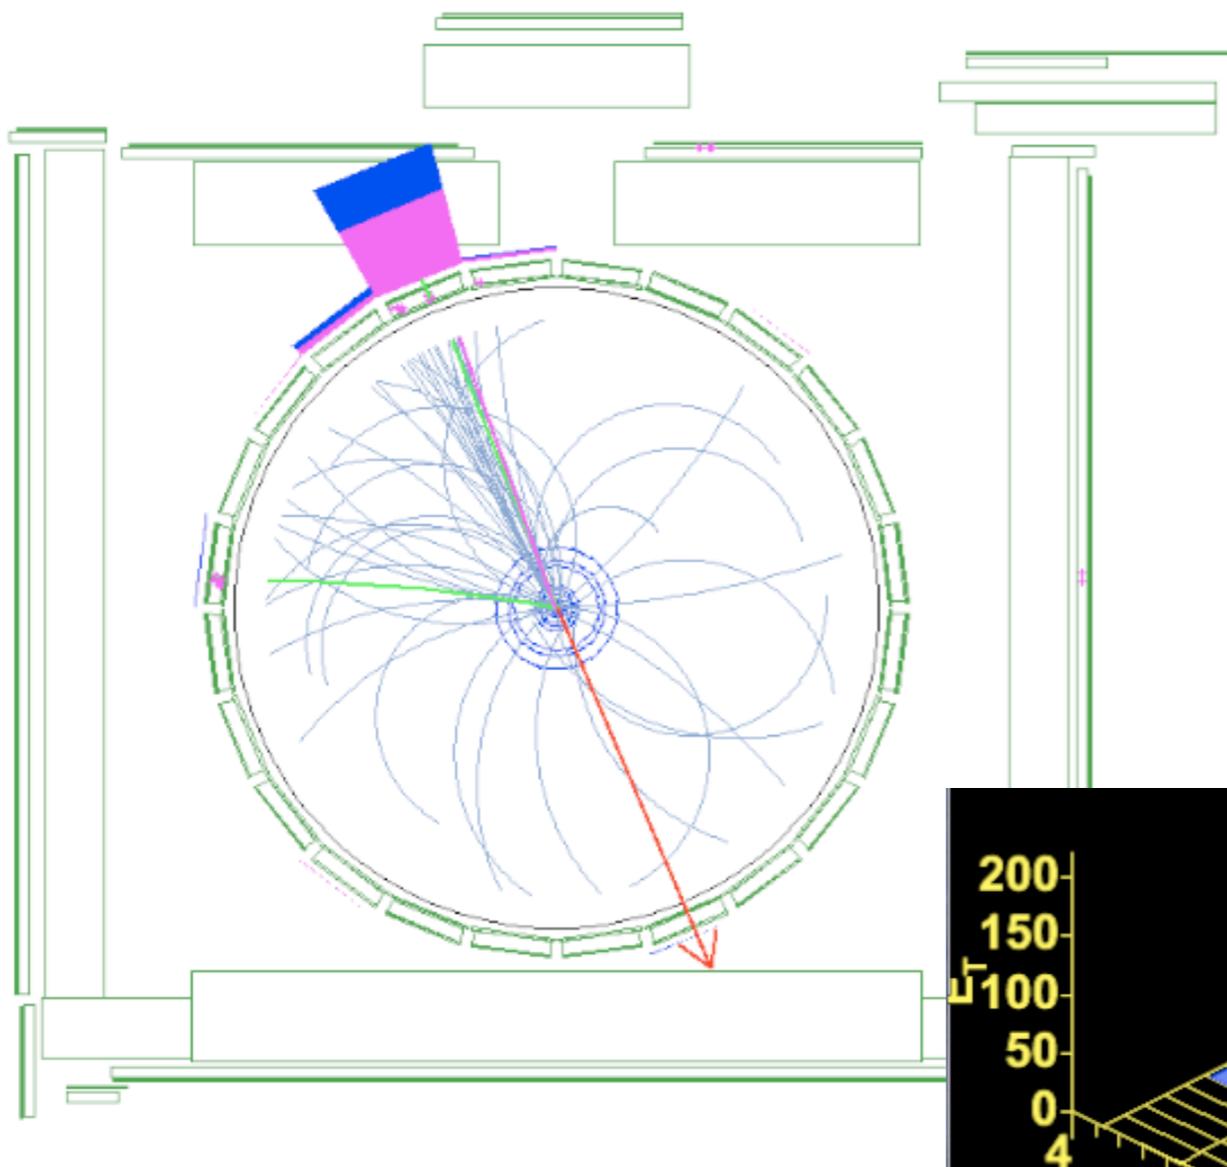

Background	Expected Events
$Z \rightarrow \nu\nu$	130 ± 14
$W \rightarrow \tau\nu$	60 ± 7
$W \rightarrow \mu\nu$	36 ± 4
$W \rightarrow e\nu$	17 ± 2
$Z \rightarrow ll$	3 ± 1
QCD	15 ± 10
Non-Collision	4 ± 4
Total Predicted	265 ± 30

E_T of Leading Jet

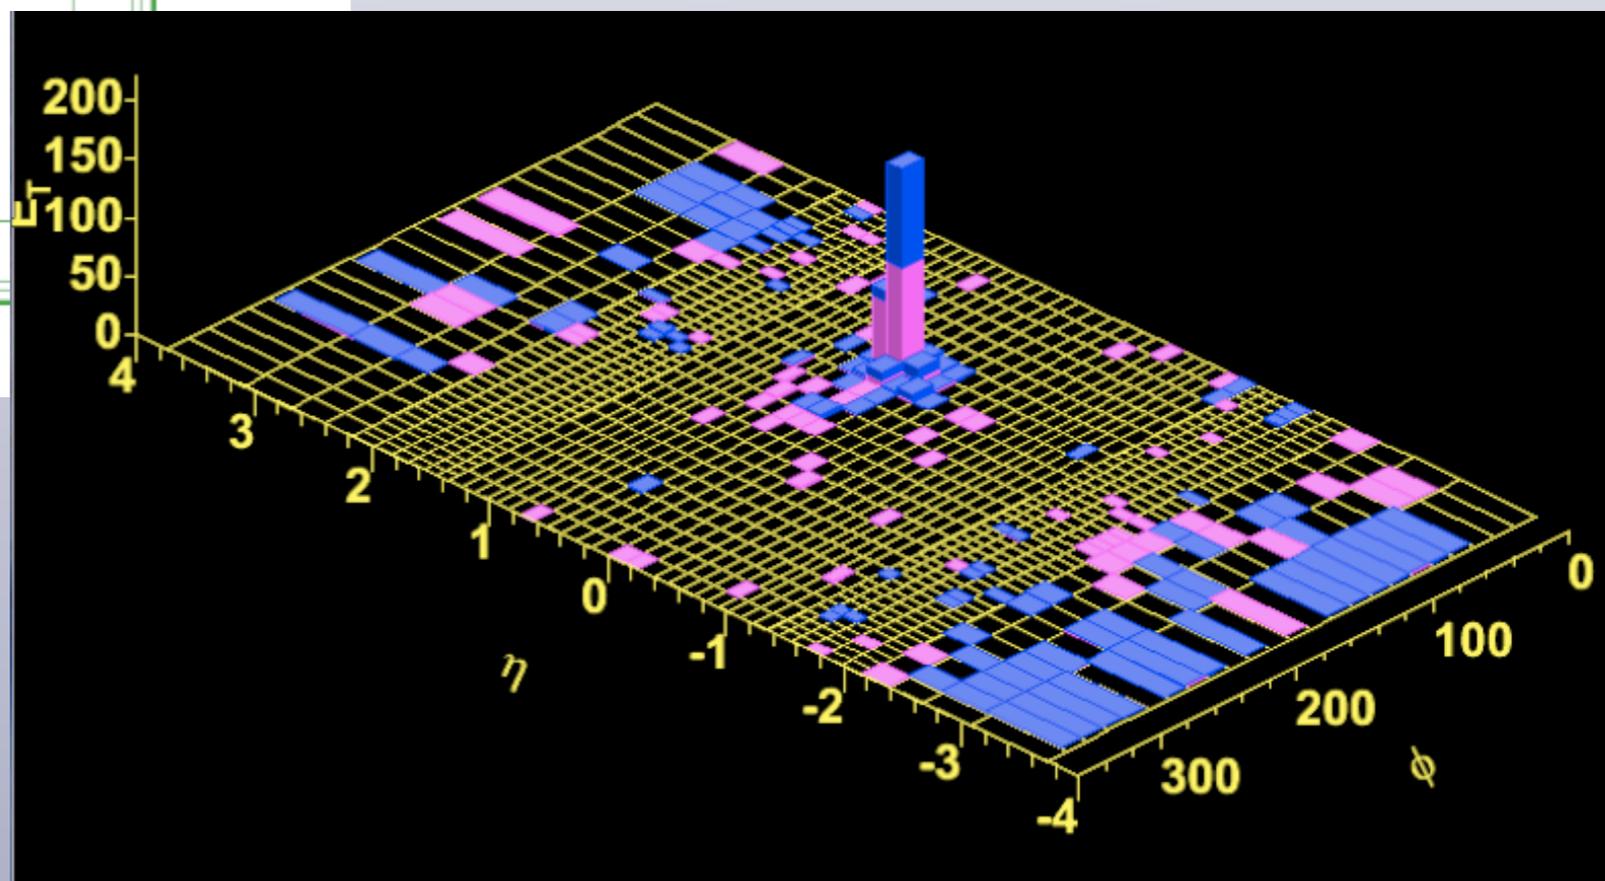

Missing E_T

-  $E_T(\text{Jet 1}) = 361 \text{ GeV}$
-  $\text{Missing } E_T = 350 \text{ GeV}$

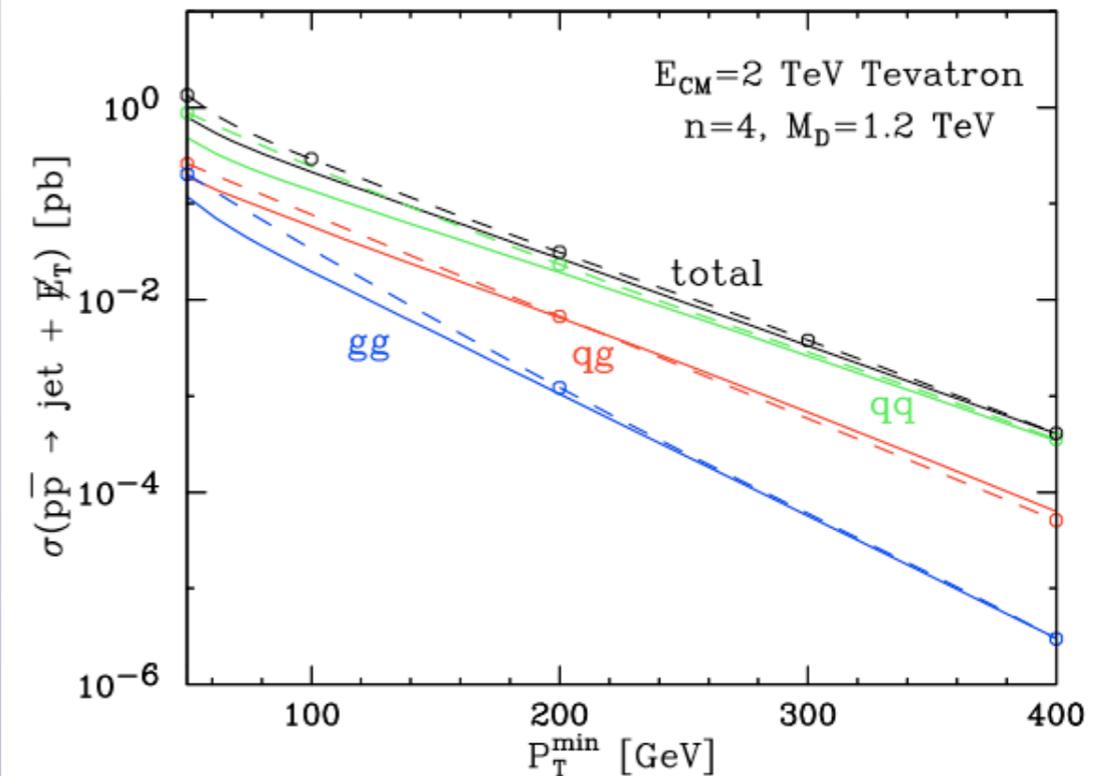

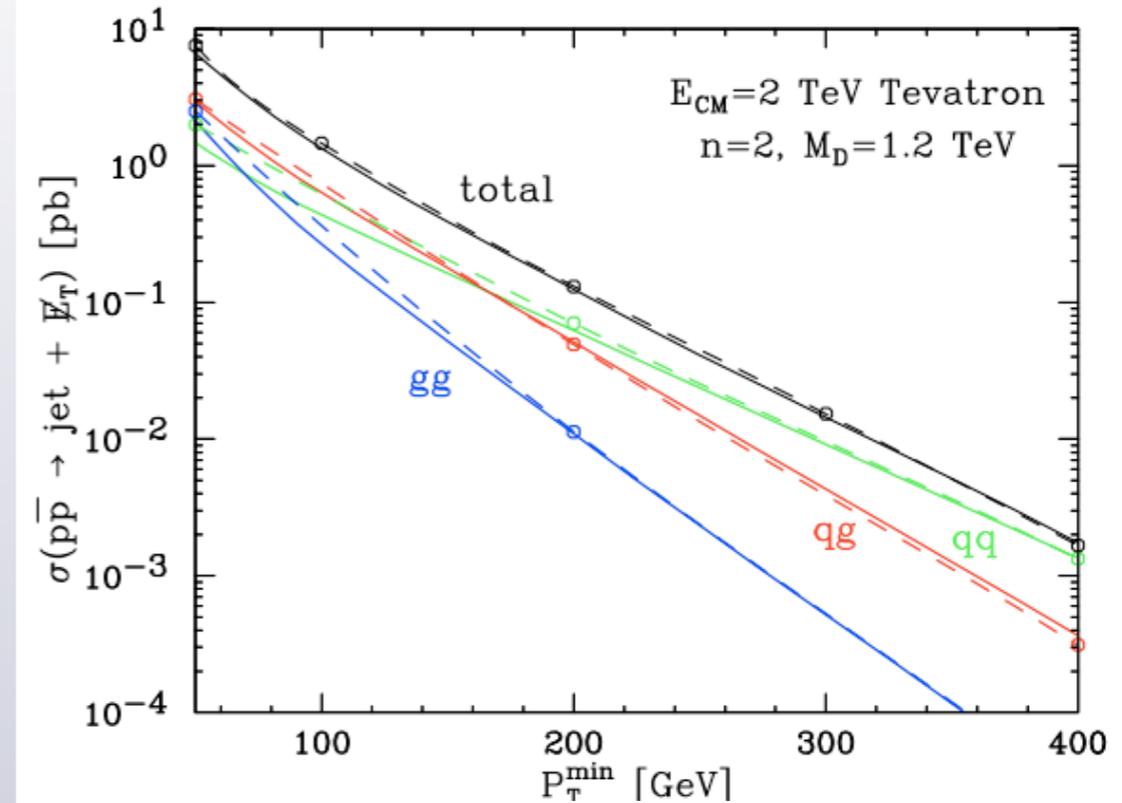

Data vs. Backgrounds

Background	Expected Events
$Z \rightarrow \nu\nu$	130 ± 14
$W \rightarrow \tau\nu$	60 ± 7
$W \rightarrow \mu\nu$	36 ± 4
$W \rightarrow e\nu$	17 ± 2
$Z \rightarrow ll$	3 ± 1
QCD	15 ± 10
Non-Collision	4 ± 4
Total Predicted	265 ± 30
Data Observed	263

- Signal MC based on calculations of GRW
- Pythia “bootleg” from Matchev and Lykken (same as used in Run1)
- Generate each of 3 processes separately for specified values of n and M_D
- Determine expected number of events for our selection

Signal Acceptance

- Total Acceptance ($P_T^{min} > 90$) $\sim 10\%$
- Acceptance is flat in M_D , slight variation with n
- Uncertainty on signal acceptance:

Source	Relative Uncertainty (%)
Jet Energy Scale	8.0
PDF	5.9
FSR	4.4
ISR	2.7
Q^2 Scale	1.9
Luminosity	6.0
MC Statistics	3.0
Total Uncertainty	13.2

Setting a Limit

- Predicted Events: 265 ± 30
- Observed Events: 263
- Upper Limit (95%CL): 70.3 events
- Convert to Limits on M_D :

n	M_D (TeV)
2	1.16
3	0.98
4	0.90
5	0.85
6	0.83

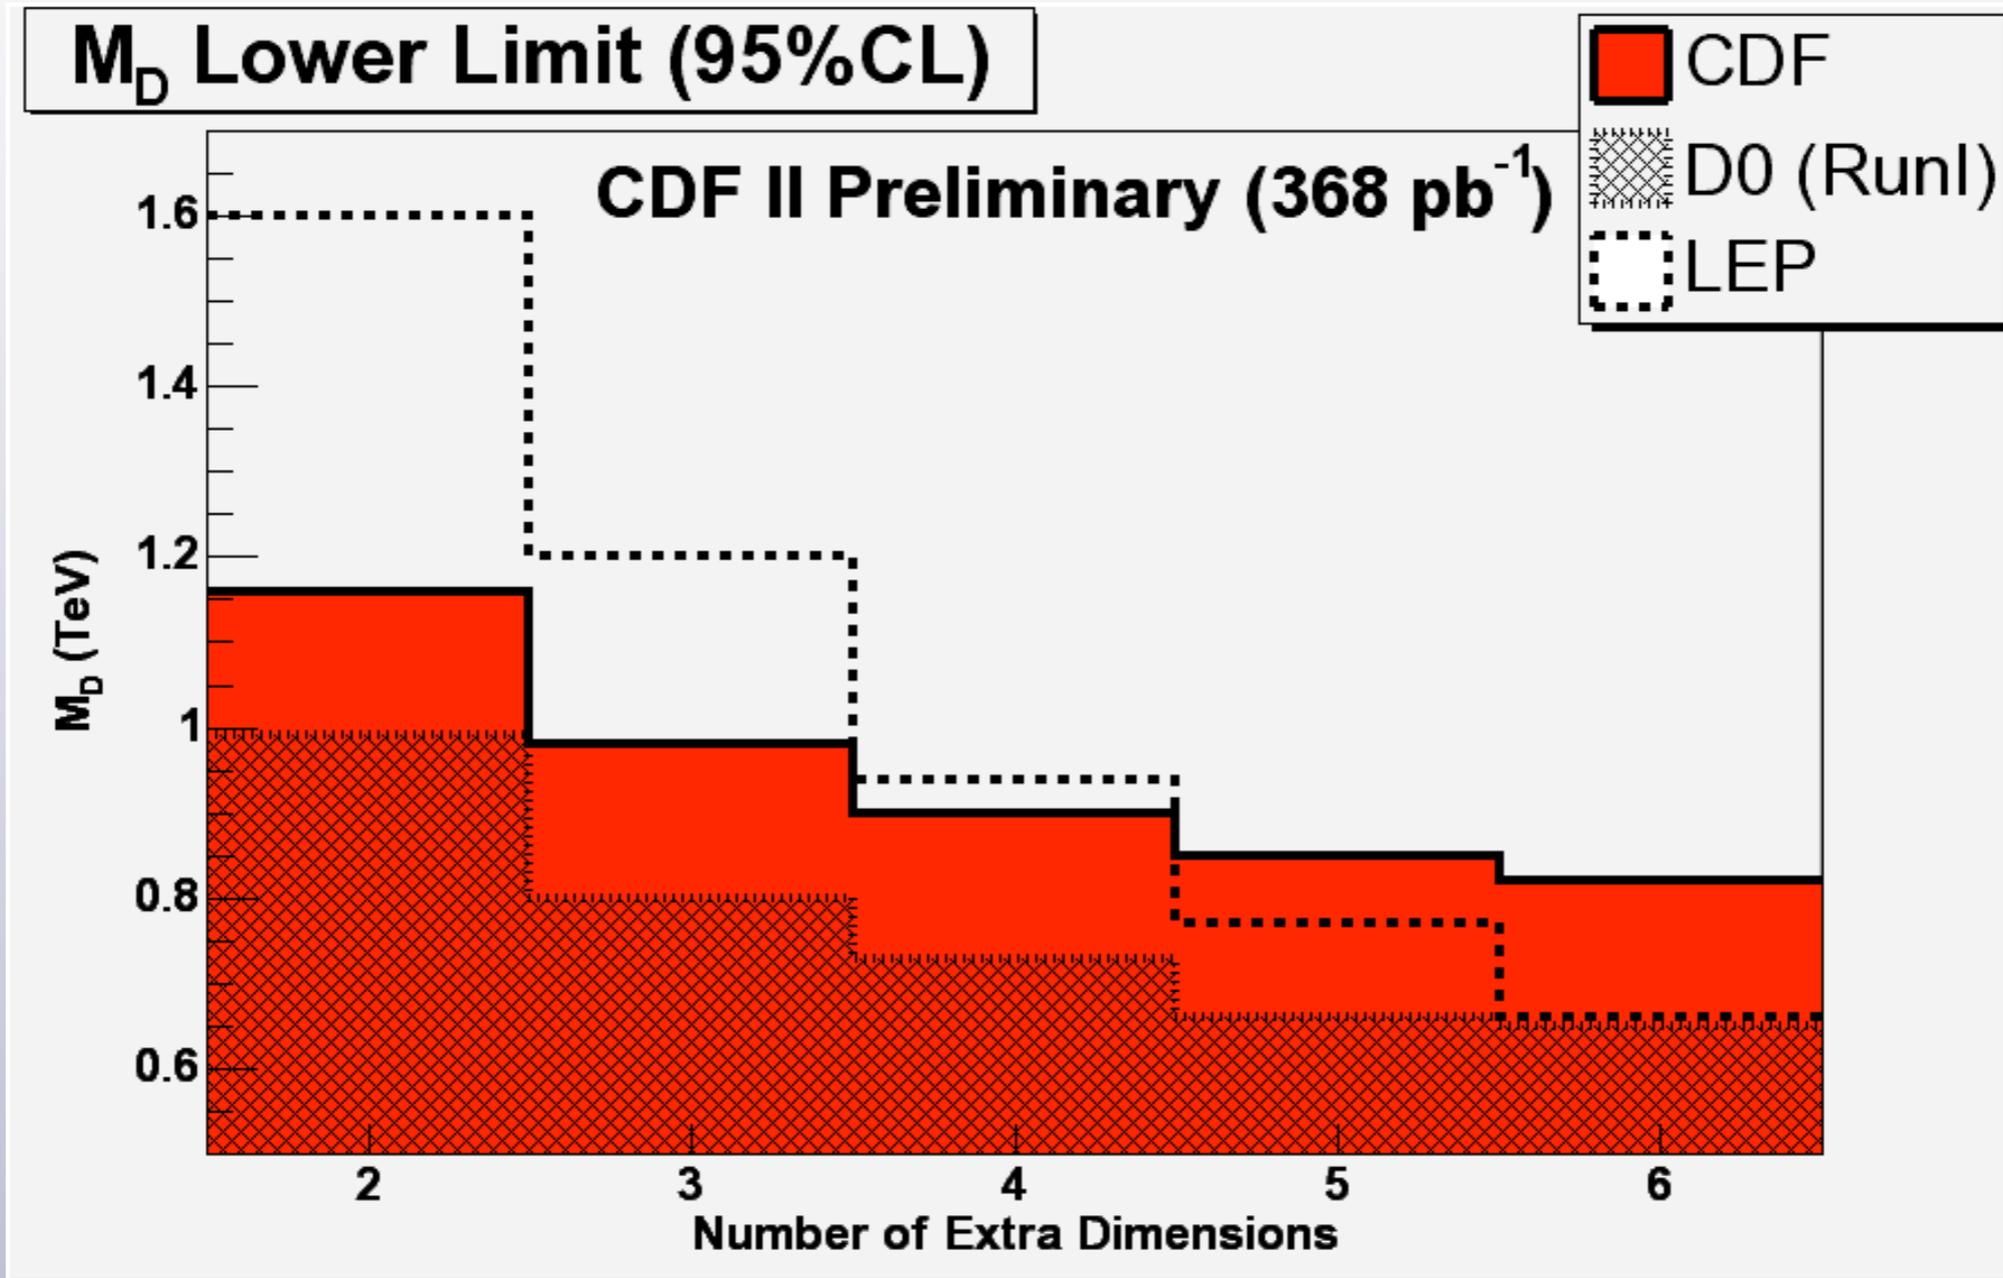

Comparisons to Other Expt's

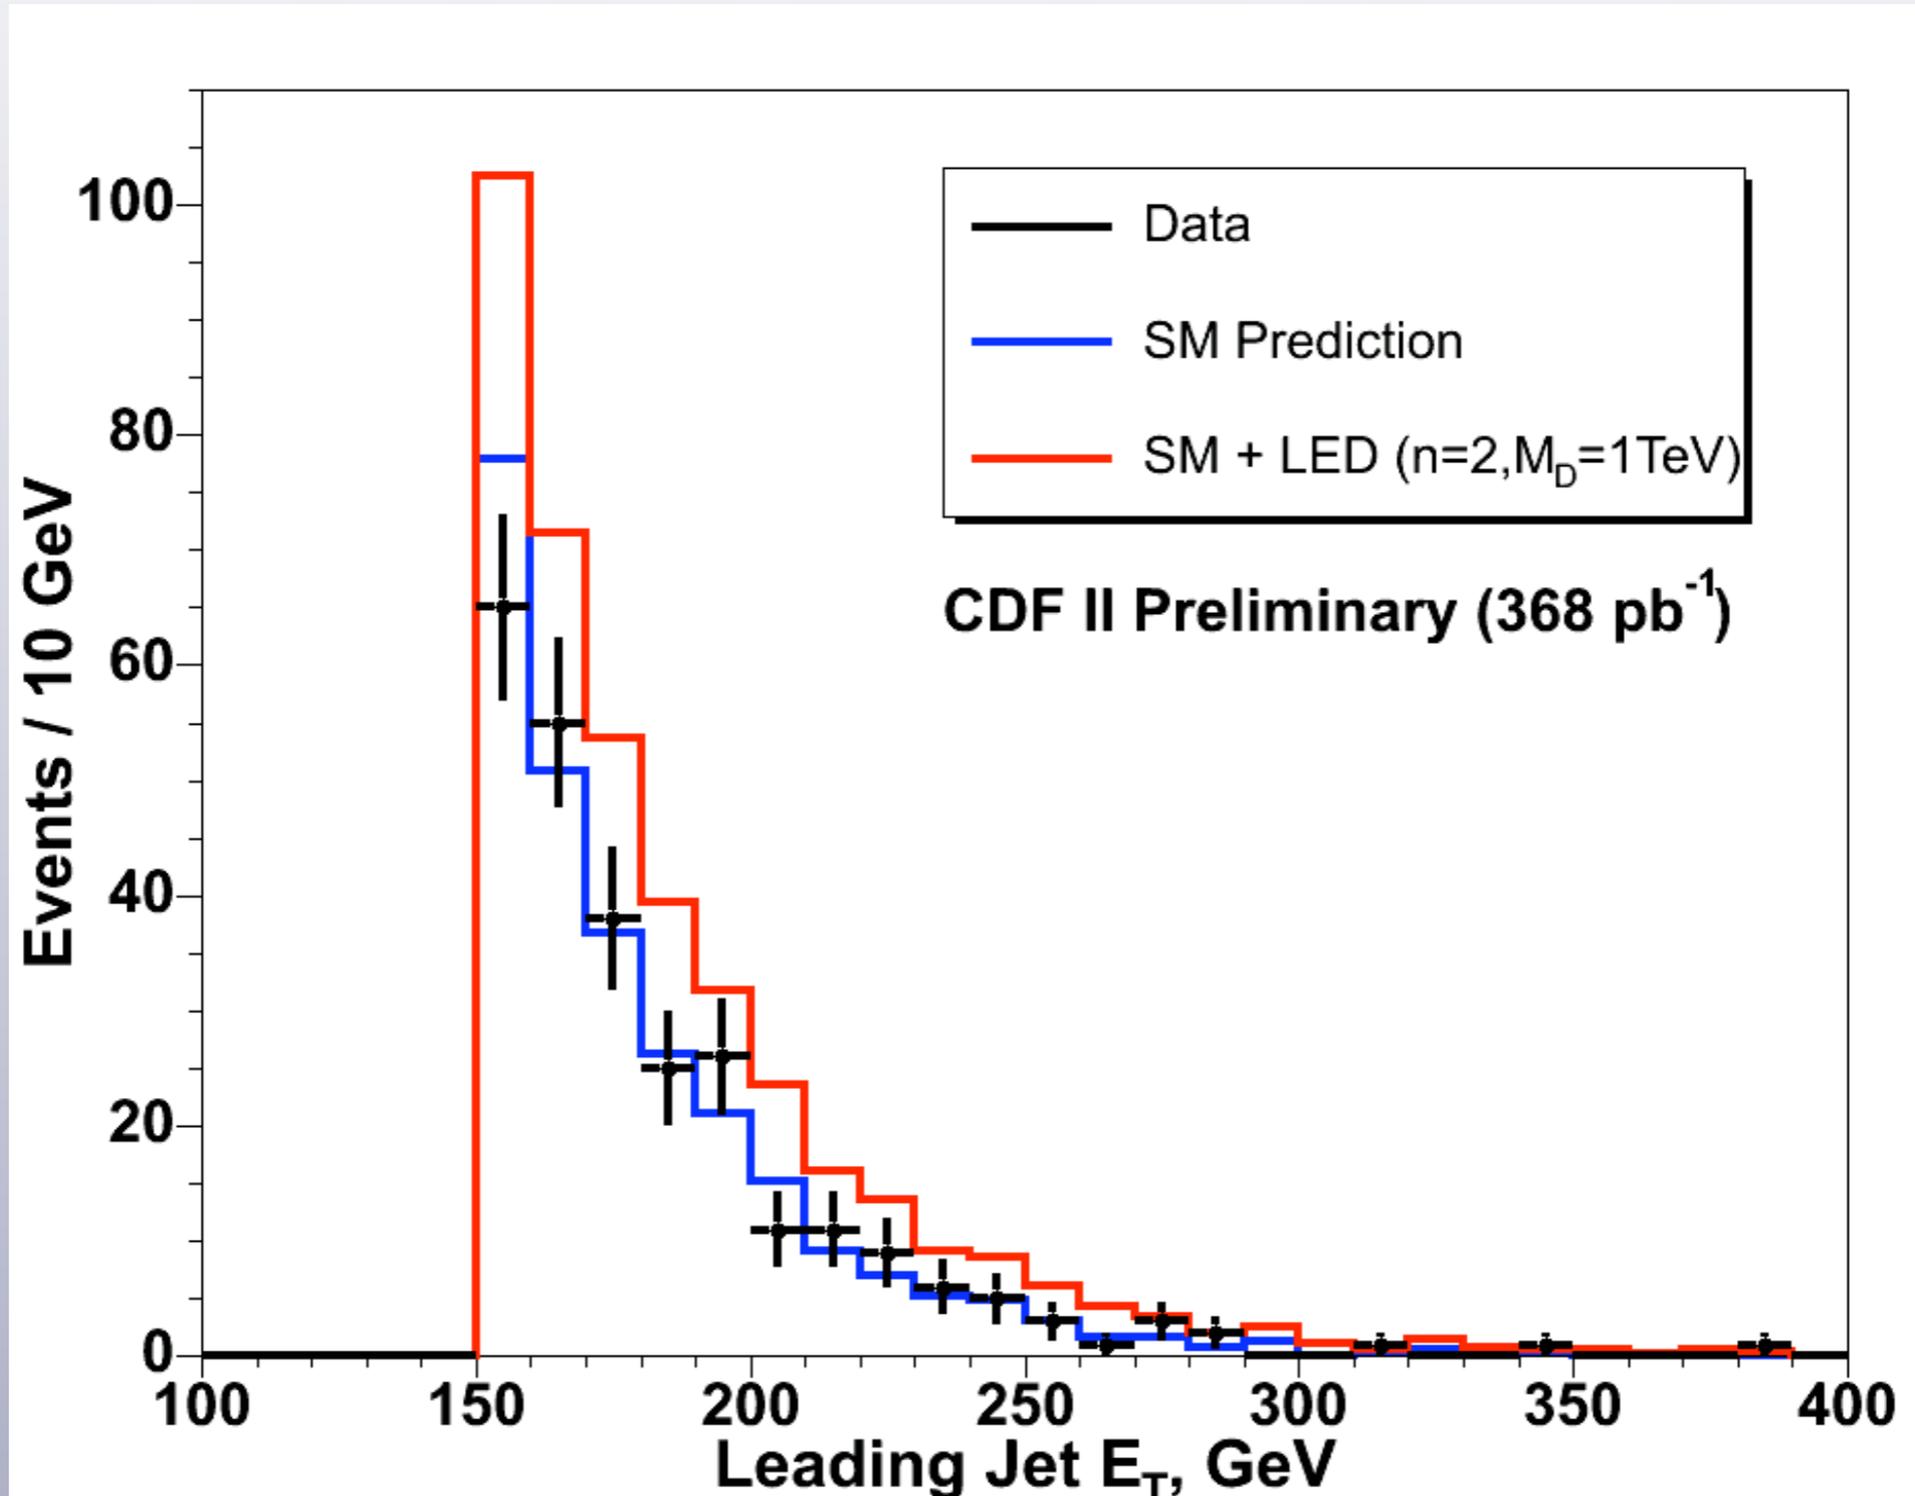

- Searches for Direct Graviton Production
- 95%CL Lower Limits on M_D (TeV)

n	CDF	D0(Run I)	LEP
2	1.16	0.99	1.60
3	0.98	0.80	1.20
4	0.90	0.73	0.94
5	0.85	0.66	0.77
6	0.83	0.65	0.66

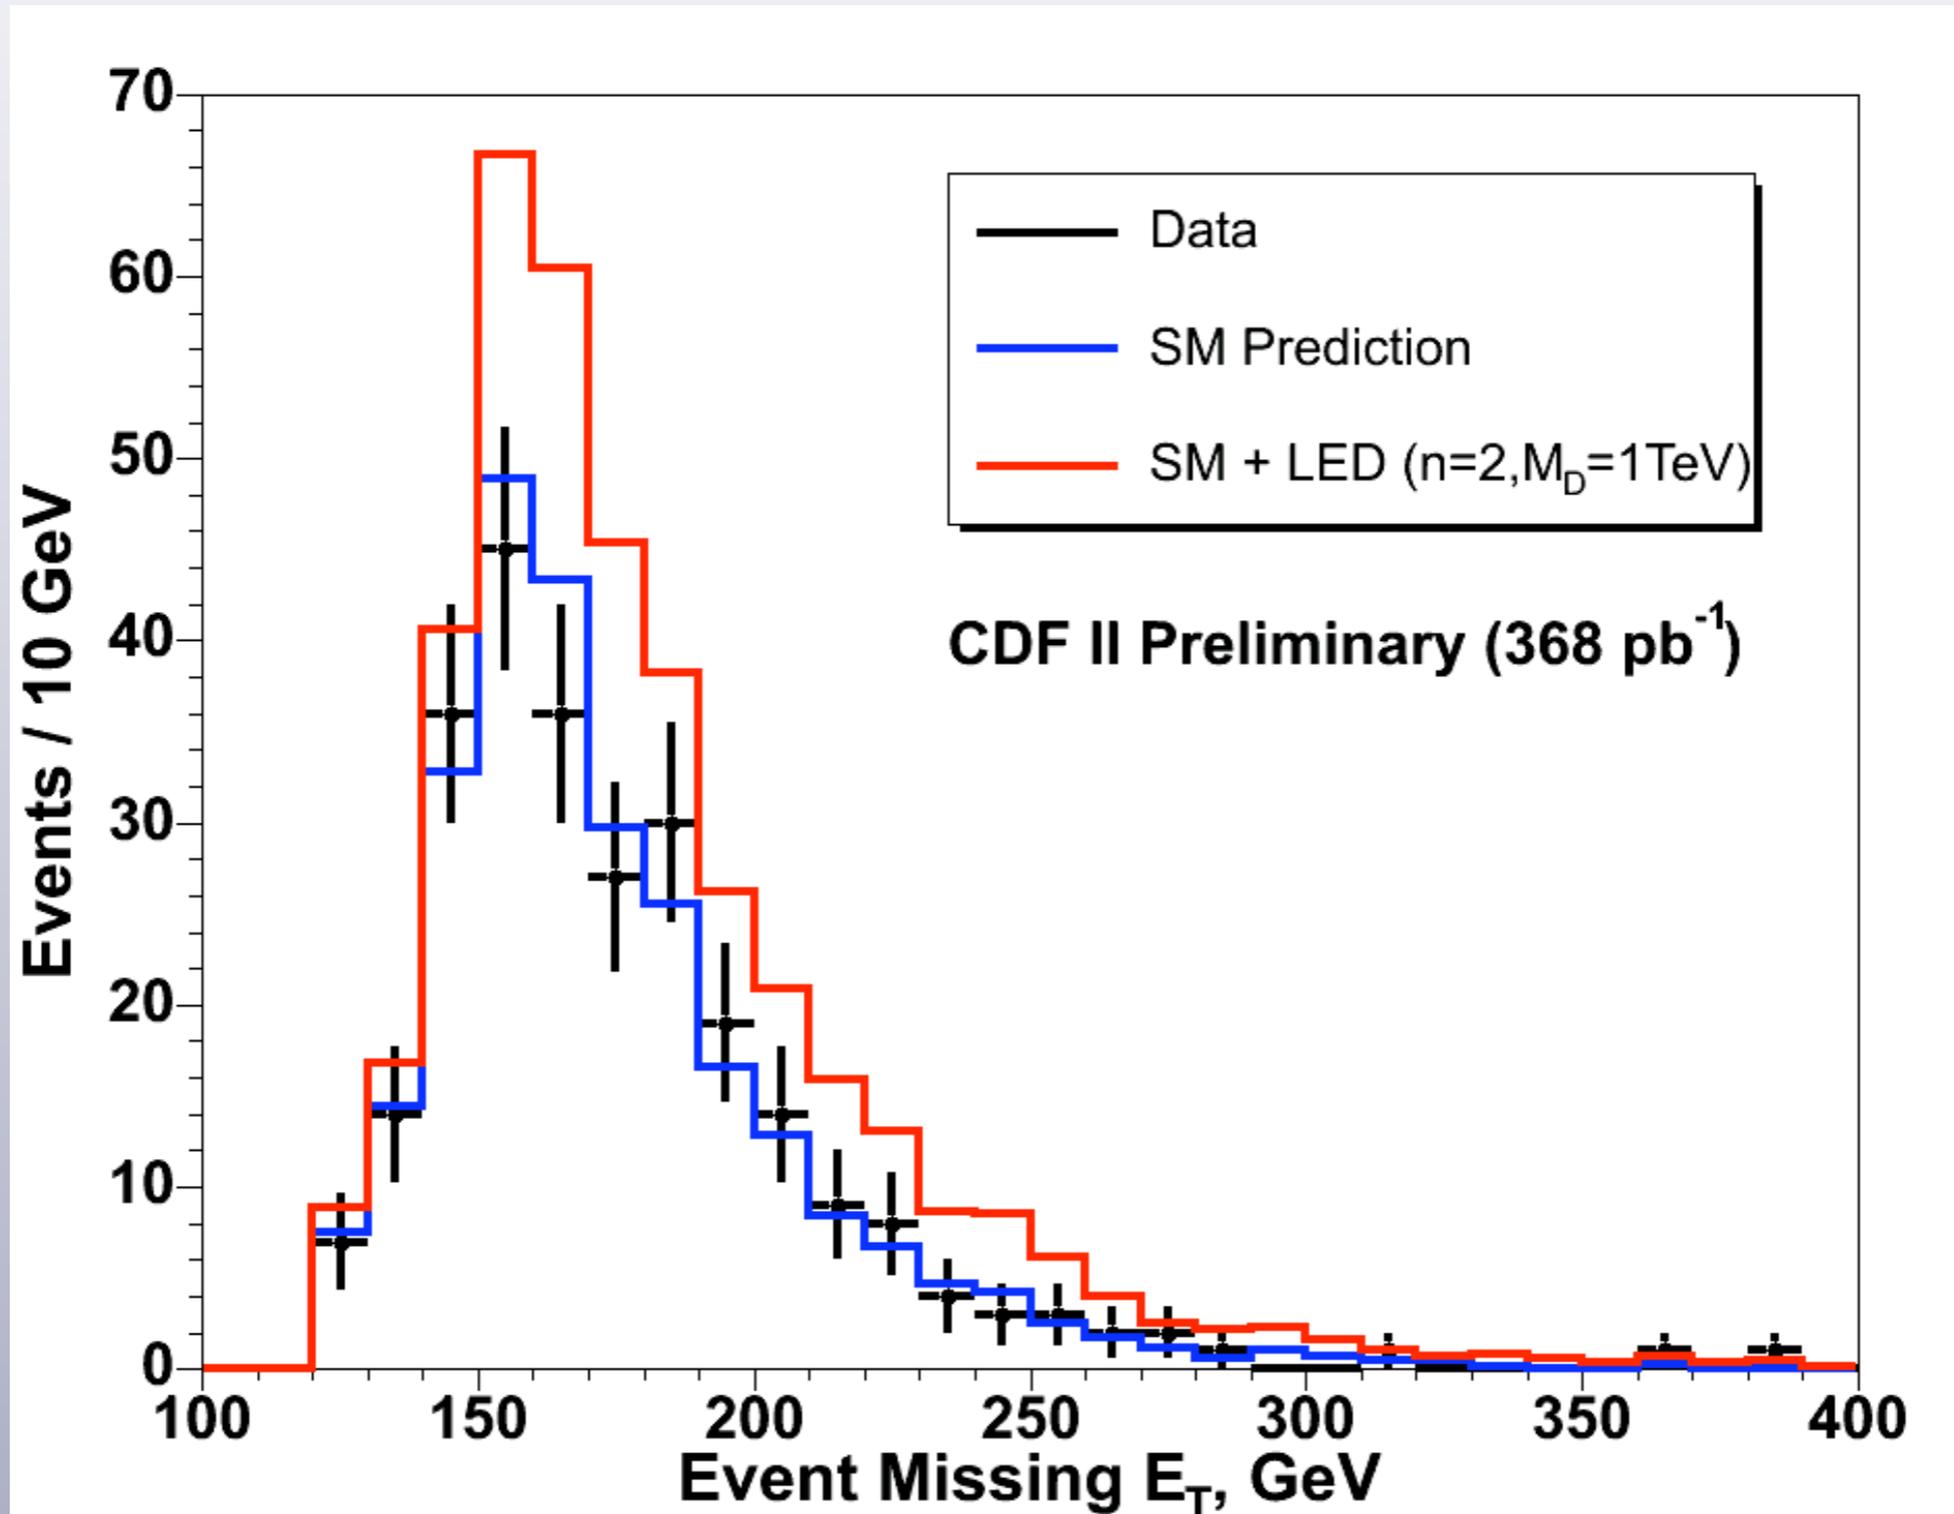

- Best limits for large values of n from CDF
- Best limits for $n=2,3$ from LEP

Add contribution for LED with $n=2, M_D=1\text{ TeV}$

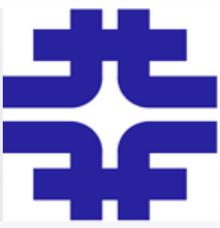

What would a signal look like?

Add contribution for LED with $n=2, M_D=1\text{ TeV}$

Limits on R

Assuming compactification on a torus,
 M_D is related to R by:

$$R^n = \frac{1}{8\pi} \left(\frac{M_{PL}}{M_D} \right)^2 \frac{1}{M_D^n}$$

Limits on R :

n	M_D (TeV/c ²)	R (mm)
2	> 1.16	< 3.6×10^{-1}
3	> 0.98	< 3.7×10^{-6}
4	> 0.90	< 1.1×10^{-7}
5	> 0.85	< 3.5×10^{-10}
6	> 0.83	< 3.4×10^{-11}

Recall: Eöt-Wash limit: $R < 1.3 \times 10^{-1}$ mm ($n=2$)

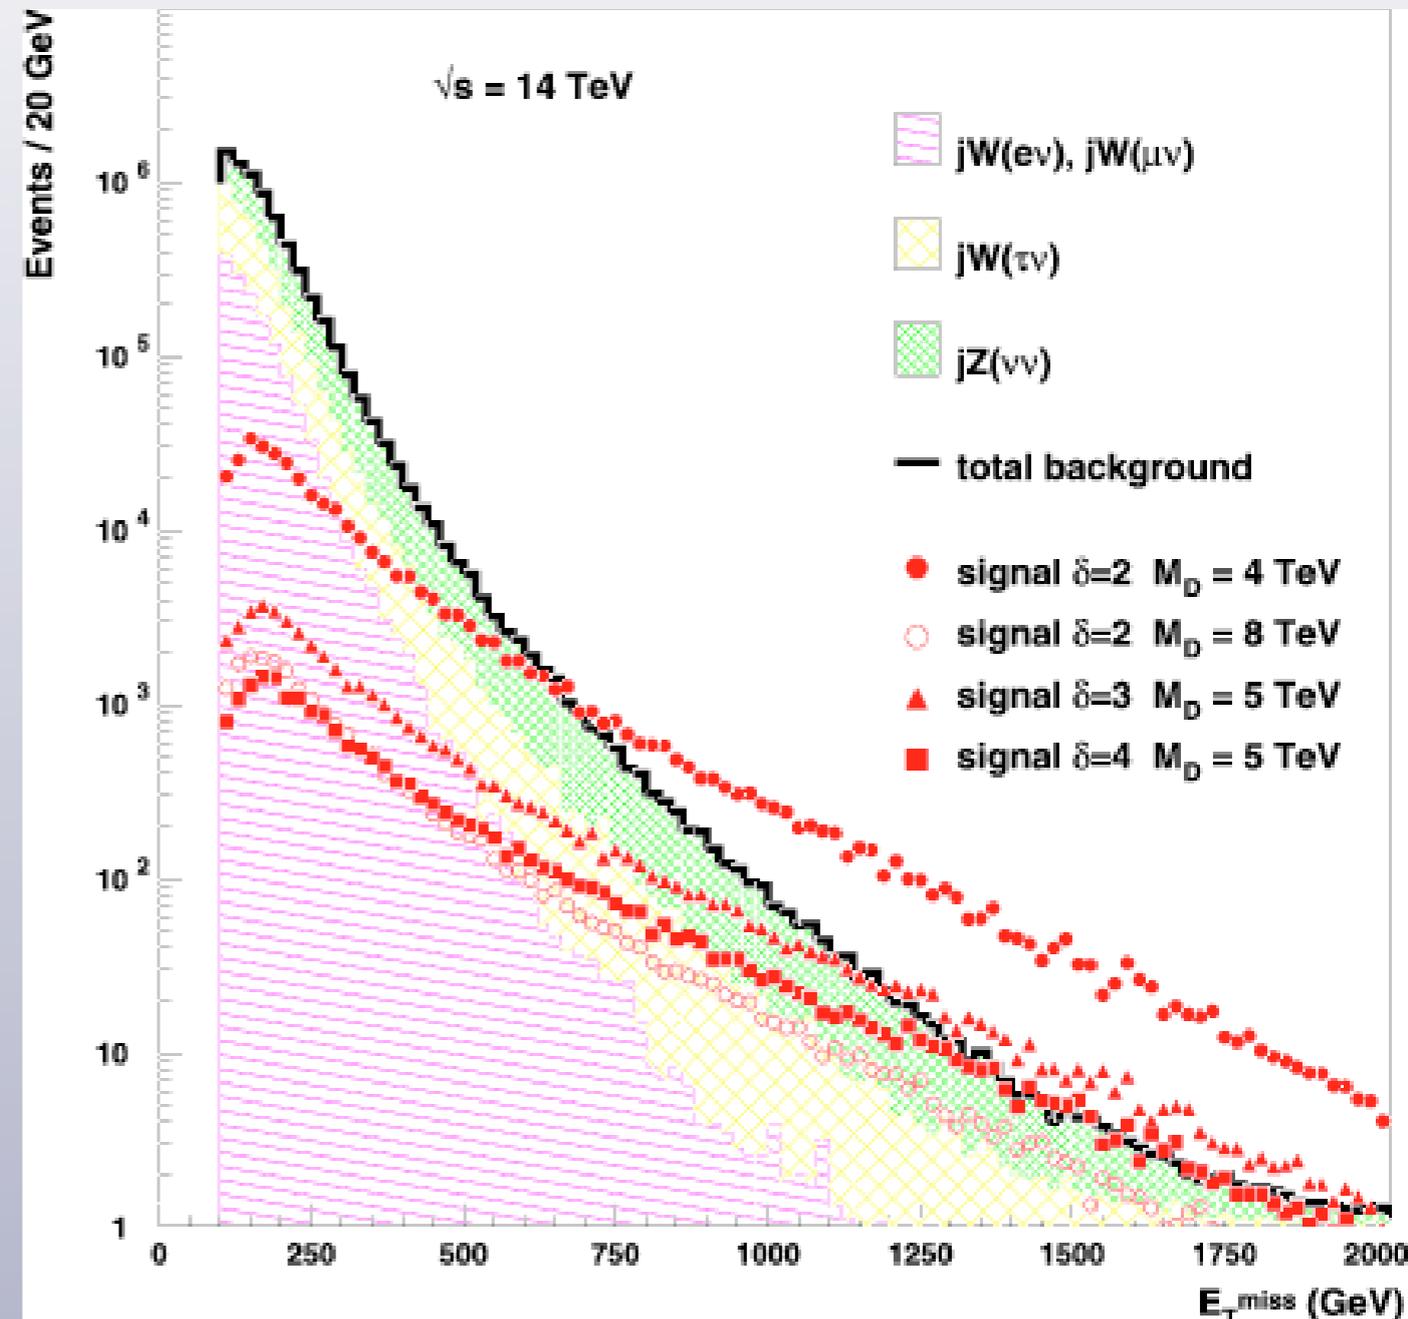

- Current analysis uses 368 pb^{-1} of data
- Because backgrounds are estimated from data, uncertainty will continue to improve with more data
- Expect updated result with 1 fb^{-1} for summer
- Additional gains using lower E_T cut and MET trigger
- Estimates of improved M_D limits with 1 fb^{-1}

n	M_D (TeV)
2	1.40
3	1.14
4	1.03
5	0.95
6	0.91

LHC can extend searches to higher values of M_D

- Have to deal with same Standard Model backgrounds
- If there is a signal, could try to determine values of n and M_D by running at different energies

n	$M_D(\text{TeV})$ <i>LL, 30 fb⁻¹</i>	$M_D(\text{TeV})$ <i>HL, 100 fb⁻¹</i>
2	7.7	9.1
3	6.2	7.0
4	5.2	6.0

(Hinchliffe, Vacavant)

- First results from CDF monojet data in RunII show good agreement with SM expectations
- In context of ADD extra dimensions models, set limits on effective Planck scale M_D
 - $M_D > 1.16 \text{ TeV}$ ($n=2$) --- $M_D > 0.83 \text{ TeV}$ ($n=6$)
 - Most stringent limits for higher values of n
 - By the end of RunII (if no discovery)
should have most stringent limits for all $n > 2$
- For higher values of n , collider searches have best sensitivity for LED, so we must continue to look
